# Working with Affymetrix data: estrogen, a $2 \times 2$ factorial design example 

June 2004

Robert Gentleman, Wolfgang Huber

1.) Preliminaries. To go through this exercise, you need to have installed $R>=1.9 .0$, the libraries Biobase, affy, hgu95av2, hgu95av2cdf, and vsn from the Bioconductor release 1.4.

```
> library(affy)
> library(estrogen)
> library(vsn)
> library(genefilter)
```

2.) Load the data.
a. Find the directory where the example cel files are. The directory path should end in
.../R/library/estrogen/extdata.
> datadir = system.file("extdata", package = "estrogen")
> datadir
[1] "/tmp/Rinst2142317929/estrogen/extdata"
> dir(datadir)
$\begin{array}{lll}\text { [1] } & \text { "bad.cel" } & \text { "estrogen.txt" } \\ \text { [5] "high48-1.cel" } & \text { "high48-2.cel" } & \text { "low10-1.cel" } \\ \text { [9] "low48-1.cel" } & \text { "low48-2.cel" } & \text { "phenoData.txt" "targLimma.txt" }\end{array}$
> setwd(datadir)
The function system.file here is used to find the subdirectory extdata of the estrogen package on your computer's harddisk. To use your own data, set datadir to the appropriate path instead.
b. The file estrogen.txt contains information on the samples that were hybridized onto the arrays. Look at it in a text editor. Again, to use your own data, you need to preprare a similar file with the appropriate information on your arrays and samples. To load it into a phenoData object

```
> pd = read.phenoData("estrogen.txt", header = TRUE, row.names = 1)
```

> pData (pd)

|  | estrogen | time.h |
| :--- | ---: | ---: |
| low10-1.cel | absent | 10 |
| low10-2.cel | absent | 10 |
| high10-1.cel | present | 10 |
| high10-2.cel | present | 10 |
| low48-1.cel | absent | 48 |
| low48-2.cel | absent | 48 |
| high48-1.cel | present | 48 |
| high48-2.cel | present | 48 |

phenoData objects are where the Bioconductor stores information about samples, for example, treatment conditions in a cell line experiment or clinical or histopathological characteristics of tissue biopsies. The header option lets the read.phenoData function know that the first line in the file contains column headings, and the row. names option indicates that the first column of the file contains the row names.
c. Load the data from the CEL files as well as the phenotypic data into an AffyBatch object.

```
> a = ReadAffy(filenames = rownames(pData(pd)), phenoData = pd,
+ verbose = TRUE)
> a
```

```
AffyBatch object
size of arrays=640x640 features (25613 kb)
cdf=HG_U95Av2 (12625 affyids)
number of samples=8
number of genes=12625
annotation=hgu95av2
```

Figure 1: see exercise 4.

## 3.) Normalization.

a. Now we can use the function expresso to normalize the data and calculate expression values.

```
> x <- expresso(a, bg.correct = FALSE, normalize.method = "vsn",
+ normalize.param = list(subsample = 1000), pmcorrect.method = "pmonly",
+ summary.method = "medianpolish")
> X
Expression Set (exprSet) with
    12625 genes
    8 samples
    phenoData object with 2 variables and 8 cases
        varLabels
            estrogen: read from file
            time.h: read from file
```

The parameter subsample determines the time consumption, as well as the precision of the calibration. The default (if you leave away the parameter normalize.param = list(subsample=1000)) is 20000; here we chose a smaller value for the sake of demonstration.
b. What are other available methods for normalization, and expression value calculation? You can consult the vignettes for the affy package for this. Choose another method (for example, MAS5 or RMA) and compare the results. For example, look at scatterplots of the probe set summaries for the same arrays between different methods.
> normalize.methods(a)
[1] "constant"
"contrasts"
"invariantset" "loess"
[5] "qspline" "quantiles" "quantiles.robust" "vsn"
> express.summary.stat.methods

```
[1] "avgdiff"
"liwong" "mas"
"medianpolish" "playerout"
```

4.) Looking at the CEL file images. The image function allows us to look at the spatial distribution of the intensities on a chip. This can be useful for quality control. Fortunately, all of the 8 celfiles that we have just loaded do not show any remarkable spatial artifacts (see Fig. 1).

```
> image(a[, 1])
```

But we have another example:

```
> badc = ReadAffy("bad.cel")
> image(badc)
```

Note that in these images, row 1 is at the bottom, and row 640 at the top.

Figure 2: see exercise 5.
5.) Histograms. Another way to visualize what is going on on a chip is to look at the histogram of its intensity distribution. Because of the large dynamical range $\left(O\left(10^{4}\right)\right)$, it is useful to look at the log-transformed values (see Fig. 2):

```
> hist(log2(intensity(a[, 4])), breaks = 100, col = "blue")
```

6.) Boxplot. To compare the intensity distribution across several chips, we can look at the boxplots, both of the raw intensities a and the normalized probe set values x (see Fig. 3):

```
> boxplot(a, col = "red")
> boxplot(data.frame(exprs(x)), col = "blue")
```

In the commands above, note the different syntax: a is an object of type AffyBatch, and the boxplot function has been programmed to know automatically what to do with it. exprs(x) is an object of type matrix. What happens if you do boxplot(x) or boxplot(exprs(x))?

```
> class(x)
[1] "exprSet"
attr(,"package")
[1] "Biobase"
```

Figure 3: see exercise 6.

```
> class(exprs(x))
```

[1] "matrix"
7.) Scatterplot. The scatterplot is a visualization that is useful for assessing the variation (or reproducibility, depending on how you look at it) between chips. We can look at all probes, the perfect match probes only, the mismatch probes only, and of course also at the normalized, probe-set-summarized data: (see Fig. 4): Why are the arrays that were made at $t=48 \mathrm{~h}$ much brighter than those at $t=10 \mathrm{~h}$ ? Look at histograms and scatterplots of the probe intensities from chips at 10 h and at 48 h to see whether you can find any evidence of saturation, changes in experimental protocol, or other quality problems. Distinguish between probes that are supposed to represent genes (you can access these e.g. through the functions pm() ) and control probes.

```
> plot(exprs(a)[, 1:2], log = "xy", pch = ".", main = "all")
> plot(pm(a)[, 1:2], log = "xy", pch = ".", main = "pm")
> plot(mm(a)[, 1:2], log = "xy", pch = ".", main = "mm")
> plot(exprs(x)[, 1:2], pch = ".", main = "x")
```

8.) Heatmap. Select the 50 genes with the highest variation (standard deviation) across chips. (see Fig. 5):

```
> rsd <- rowSds(exprs(x))
> sel <- order(rsd, decreasing = TRUE)[1:50]
```

Figure 4: see exercise 7.
> heatmap(exprs(x)[sel, ], col = gentlecol(256))
9.) ANOVA. Now we can start analysing our data for biological effects. We set up a linear model with main effects for the level of estrogen (estrogen) and the time (time.h). Both are factors with 2 levels.
> lm.coef = function(y) lm(y ~ estrogen * time.h)\$coefficients
> eff = esApply(x, 1, lm.coef)
For each gene, we obtain the fitted coefficients for main effects and interaction:
$>\operatorname{dim}(e f f)$
[1] 412625
> rownames (eff)

Figure 5: see exercise 8.

```
[1] "(Intercept)" "estrogenpresent" "time.h"
[4] "estrogenpresent:time.h"
```

```
> affyids <- colnames(eff)
```

```
> affyids <- colnames(eff)
```

Let's bring up the mapping from the vendor's probe set identifier to gene names.

```
> library(hgu95av2)
> ls("package:hgu95av2")
```

[1] "hgu95av2"
[4] "hgu95av2CHRLENGTHS"
[7] "hgu95av2ENZYME"
[10] "hgu95av2GO"
[13] "hgu95av2LOCUSID"
[16] "hgu95av20MIM"
[19] "hgu95av2PATH2PROBE"
[22] "hgu95av2PMID2PROBE"
[25] "hgu95av2QCDATA"
[28] "hgu95av2SYMBOL"
"hgu95av2ACCNUM" "hgu95av2CHR"
"hgu95av2CHRLOC" "hgu95av2ENTREZID"
"hgu95av2ENZYME2PROBE" "hgu95av2GENENAME"
"hgu95av2GO2ALLPROBES" "hgu95av2GO2PROBE"
"hgu95av2MAP"
"hgu95av20RGANISM"
"hgu95av2PFAM"
"hgu95av2PROSITE"
"hgu95av2REFSEQ"
"hgu95av2UNIGENE"
"hgu95av2MAPCOUNTS"
"hgu95av2PATH"
"hgu95av2PMID"
"hgu95av2QC"
"hgu95av2SUMFUNC"

Let's now first look at the estrogen main effect, and print the top 3 genes with largest effect in one direction, as well as in the other direction. Then, look at the estrogen:time interaction.

## estrogen main effect

Figure 6: see exercise 9.

```
> lowest <- sort(eff[2, ], decreasing = FALSE) [1:3]
> mget(names(lowest), hgu95av2GENENAME)
