

Drug versus Disease data package

1 Introduction

The Drug versus Disease data package provides reference data set for the DrugVsDisease package which is a pipeline for the comparison of drug and disease gene expression profiles where negatively correlated (enriched) profiles can be used to generate hypotheses of drug-repurposing and positively correlated (enriched) profiles may be used to infer side-effects of drugs. The reference data includes disease and drug profiles, where the disease profiles were manually curated from experiments available from the Gene Expression Omnibus (GEO)

1.1 Disease Signatures

Datasets included in the DrugVsDiseasedata reference set contained disease versus control samples that were derived from disease-relevant primary tissues. In total, 85 disease-associated microarray experiments (disease vs control) were acquired to represent and characterise 45 distinct diseases with (3766) individual microarrays. These were obtained from NCBI GEO microarray repository [http:// www.ncbi.nlm.nih.gov/geo/](http://www.ncbi.nlm.nih.gov/geo/).

The raw CEL files were normalised using rma and probes mapped to genes using the average ranking method. The pairwise similarity score matrix of these profiles was generated using the top and bottom 100 genes and Affinity propagation used to derive a network of disease connections, the classifications of each disease profile is given in the diseaseClusters data file. The 88 profiles resulted in a network of 12 clusters, the ranked profiles used to generate these networks are stored in the diseaseRL data object.

```
> #to load the disease ranked profiles
> data(diseaseRL, package="DrugVsDiseasedata")
```

1.2 Annotation

The DrugVsDisease data package automatically downloads and annotates Affymetrix probe sets to HUGO gene symbols using biomaRt. The annotationlist in DrugVsDiseasedata gives the Affymetrix platform annotation and associated database reference in BiomaRt to allow for automatic detection and calculation. The genes which are in the intersection of the three Affymetrix platforms supported for automatic annotation by DrugVsDisease are given in the genelist object.

```
> data(annotationlist, package="DrugVsDiseasedata")
> #to get the HUGO genes which are included in the reference data
> data(genelist, package="DrugVsDiseasedata")
```

1.3 GEO data

The meta information is processed in DrugVsDisease through the GEOquery package. This provides the experimental design, for DrugVsDisease this information is used to identify explanatory factors which may be used in a regression model. The list of available factor values which are available on the GEO website <http://www.ncbi.nlm.nih.gov/geo/> are stored in the GEOfactorvalues object for use by DrugVsDisease.

```
> data(GEOfactorvalues, package="DrugVsDiseasedata")
```

1.4 Cytoscape Information

An associated cytoscape plug-in is available for DrugVsDisease which also uses the DrugVsDisease-data package. The DrugVsDisease-data package contains the cytodisease data object which contains the edges in the network along with the distance and Running sum Peak Statistic (RPS). The latter two are used as edge attributes by Cytoscape. The Running sum Peak Statistic takes values 1 or -1 where 1 indicates a positive correlation and -1 a negative correlation. The distance measure gives the strength of this correlation. This data frame is used by the DrugVsDisease package to generate cytoscape sif and edge attribute files. For links out to the MeSH external web browsers, DrugVsDisease-data also contains search compatible terms for all nodes in the reference data sets.

```
> data(cytodisease,package="DrugVsDisease-data")
> #to get the compound (node) names and corresponding search terms
> data(diseaselabels,package="DrugVsDisease-data")
```
