# General Analysis of Tiling Microarray Data

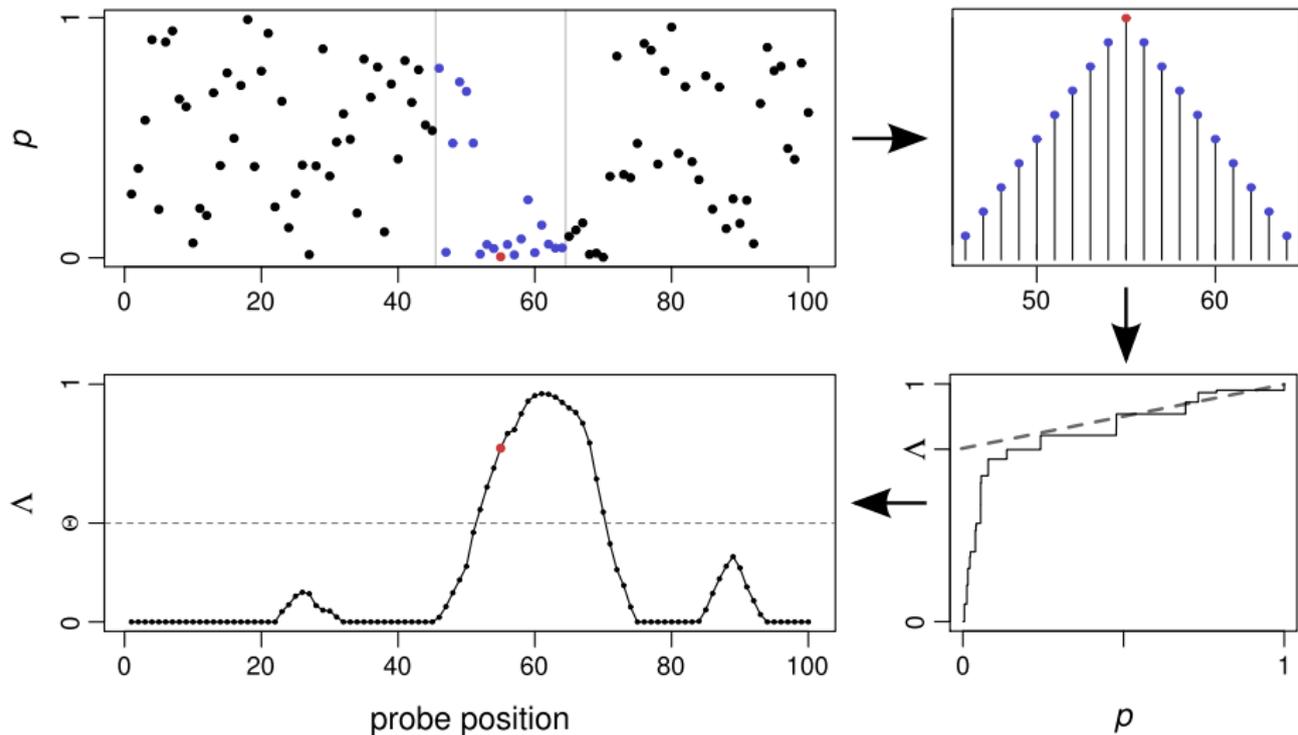

analysis of differential design experiments

- assessing the effect for each probe individually

- combining information of neighboring probes

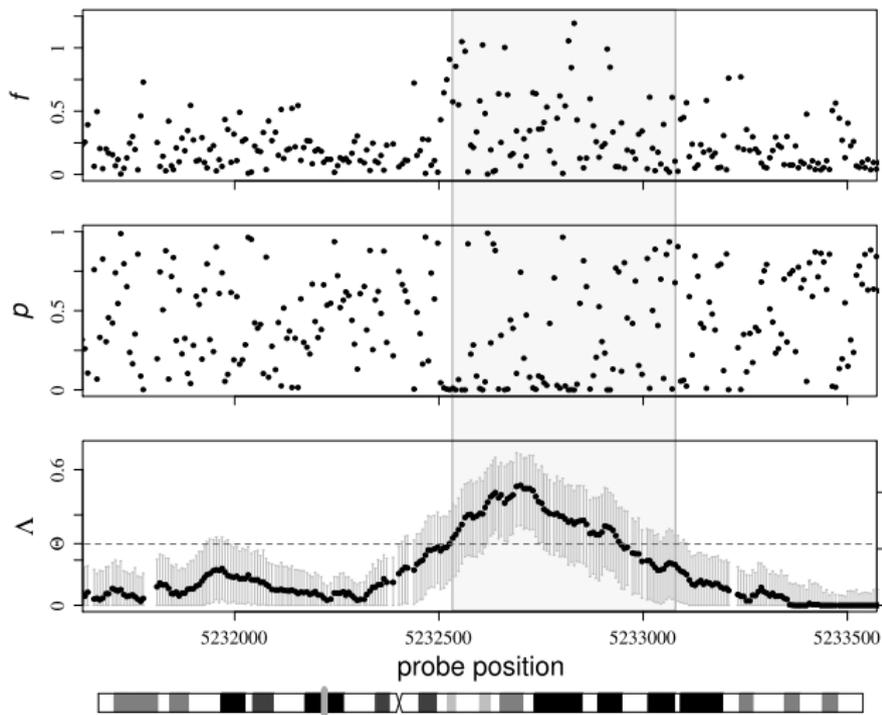

# From Probe Level p-values to Loci of Enhanced Significance

# Characteristics of the LES Approach

- estimator for the fraction of significant probes in the local surrounding of the genome
- confidence intervals computed with bootstrapping
- statistics allow a meaningful interpretation
- independent of the analysis at the probe level
- accounts for the dependency of probes through weighting, flexible in the definition of the weighting window
- all parameters can be estimated from the data

# Results for ChIP-chip Data

data: Johnson et al., 2008

## *les* package

- identification of differential effects in tiling microarray experiments based on probe-level p-values
- features:
  - object oriented, S4 classes
  - high-level plotting
  - export of results to standard formats
  - scalable, speed and memory efficient
  - support of multicore processing
- published with bioconductor release 2.7 in October 2010

## Usage of the *les* Package

```
library(les)
```

```
x <- Les(pos, pval, chr)
```

```
x <- estimate(x, weighting=rectangWeight, win=100, ...)
```

```
x <- ci(x, conf=0.95, ...)
```

```
x <- threshold(x, ...)
```

```
x <- regions(x, ...)
```

```
region <- x[“regions”]
```

```
export(x, file, format, ...)
```

```
plot(x, ...)
```
