# Package 'simplifyEnrichment'

July 26, 2025

Type Package

```
Title Simplify Functional Enrichment Results
Version 2.3.0
Date 2024-09-13
Depends R (>= 4.0.0)
Imports simona, ComplexHeatmap (>= 2.7.4), grid, circlize, GetoptLong,
      digest, tm, GO.db, AnnotationDbi, slam, methods, clue,
      grDevices, stats, utils, cluster (>= 1.14.2), colorspace,
      GlobalOptions (>= 0.1.0)
Suggests knitr, ggplot2, cowplot, mclust, apcluster, MCL, dbscan,
      igraph, gridExtra, dynamicTreeCut, testthat, gridGraphics,
      flexclust, BiocManager, InteractiveComplexHeatmap (>= 0.99.11),
      shiny, shinydashboard, cola, hu6800.db, rmarkdown, genefilter,
      gridtext, fpc
Description
      A new clustering algorithm, ``binary cut", for clustering similarity matrices of functional terms
      is implemeted in this package. It also provides functions for visualizing, summarizing and com-
      paring the clusterings.
biocViews Software, Visualization, GO, Clustering, GeneSetEnrichment

 $anno\_word\_cloud$ 

Word cloud annotations

# Description

Word cloud annotations

```
anno_word_cloud(
  align_to,
  term,
  exclude_words = NULL,
  max_words = 10,
  word_cloud_grob_param = list(),
  fontsize_range = c(4, 16),
  value_range = NULL,
  bg_gp = gpar(fill = "#DDDDDD", col = "#AAAAAA"),
  side = c("right", "left"),
  add_new_line = FALSE,
  count_words_param = list(),
  ...,
  return_gbl = FALSE
)
```

anno\_word\_cloud 3

### **Arguments**

align\_to

How to align the annotations to the heatmap. Similar as in ComplexHeatmap::anno\_link, the value of align\_to can be a list of row indices or a categorical vector where each vector in the list corresponds to a word cloud. If it is a categorical vector, rows with the same level correspond to a same word cloud. If align\_to is a categorical vector and term is a list, names of term should have overlap to the levels in align\_to. When align\_to is set as a categorical vector, normally the same value is set to row\_split in the main heatmap so that each row slice can correspond to a word cloud.

term

The description text used for constructing the word clouds. The value should have the same format as align\_to. If align\_to is a list, term should also be a list. In this case, the length of vectors in term is not necessarily the same as in align\_to. E.g. length(term[[1]]) is not necessarily equal to length(align\_to[[1]]]. If align\_to is a categorical vector, term should also be a character vector with the same length as align\_to. To make it more genrall, when align\_to is a list, term can also be a list of data frames where the first column contains keywords and the second column contains numeric values that will be mapped to font sizes in the word clouds.

exclude\_words The words excluded for construcing word cloud.

max\_words Maximal number of words visualized in the word cloud.

word\_cloud\_grob\_param

A list of graphics parameters passed to word\_cloud\_grob.

fontsize\_range The range of the font size. The value should be a numeric vector with length

two. The font size interpolation is linear.

value\_range The range of values to map to font sizes.

bg\_gp Graphics parameters for controlling the background.

side Side of the annotation relative to the heatmap.

add\_new\_line Whether to add new line after every word? If TRUE, each word will be in a

separated line.

count\_words\_param

A list of parameters passed to count\_words.

... Other parameters. return\_gbl Internally used.

# Details

The word cloud annotation is constructed by ComplexHeatmap::anno\_link.

If the annotation is failed to construct or no keyword is found, the function returns a ComplexHeatmap::anno\_empty with 1px width.

English stop words, punctuation and numbers are removed by default when counting words. As specific stop words might coincide with gene or pathway names, and numbers in genes names might be meaningful it is recommended to adjust this behaviour by passing appropriate arguments to the count\_words function using count\_words\_param.

```
gm = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
go_id = rownames(gm)
go_term = AnnotationDbi::select(GO.db::GO.db, keys = go_id, columns = "TERM")$TERM
```

```
split = sample(letters[1:4], 100, replace = TRUE)
align_to = split(1:100, split)
term = lapply(letters[1:4], function(x) sample(go_term, sample(100:400, 1)))
names(term) = letters[1:4]

require(ComplexHeatmap)
mat = matrix(rnorm(100*10), nrow = 100)
Heatmap(mat, cluster_rows = FALSE, row_split = split,
    right_annotation = rowAnnotation(foo = anno_word_cloud(align_to, term)))
```

anno\_word\_cloud\_from\_GO

Word cloud annotations from GO

# Description

Word cloud annotations from GO

# Usage

```
anno_word_cloud_from_GO(
   align_to,
   go_id,
   stat = c("pvalue", "count"),
   min_stat = ifelse(stat == "count", 5, 0.05),
   term = NULL,
   exclude_words = NULL,
   ...
)
```

# Arguments

align_to	The same format as in anno_word_cloud.		
go_id	The value should be in the same format as align_to. If go_id is a verification it should have the same length as align_to, and if go_id is a list, note length(go_id[[1]]) is not necessarily equal to length(align_to[[1]]) align_to is a categorical vector and go_id is a list, names of go_id shave overlap to the levels in align_to.		
stat	What type of value to map to font sizes of the keywords. There are two possible values. "pvalue": enrichment is applied to keywords and -log10(p-value) is used to map to font size; "count": simply word frequency of keywords.		
min_stat	Minimal value for stat for selecting keywords.		
term	Alternatively the GO description can be set via the term argument. The same format as in anno_word_cloud.		
exclude_words	The words excluded for construcing word cloud. Some words are internally excluded: c("via", "protein", "factor", "side", "type", "specific").		
	All other arguments passed to anno_word_cloud.		

area\_above\_ecdf 5

area\_above\_ecdf

Area above the eCDF curve

### **Description**

Area above the eCDF curve

### Usage

```
area_above_ecdf(x)
```

# **Arguments**

Х

A vector of similarity values.

#### **Details**

Denote F(x) as the eCDF (empirical Cumulative Distribution Function) of the similarity vector x, this function calculates the area above the eCDF curve, which is  $1 - \int -\int -\int x^1 dx$ .

#### Value

A numeric value.

cluster\_terms

Cluster terms based on their similarity matrix

### **Description**

Cluster terms based on their similarity matrix

```
cluster_terms(
    mat,
    method = "binary_cut",
    control = list(),
    verbose = se_opt$verbose
)

cluster_by_kmeans(mat, max_k = max(2, min(round(nrow(mat)/5), 100)), ...)

cluster_by_pam(mat, max_k = max(2, min(round(nrow(mat)/10), 100)), ...)

cluster_by_dynamicTreeCut(mat, minClusterSize = 5, ...)

cluster_by_fast_greedy(mat, ...)

cluster_by_leading_eigen(mat, ...)
```

6 cluster\_terms

```
cluster_by_louvain(mat, ...)
cluster_by_walktrap(mat, ...)
cluster_by_mclust(mat, G = seq_len(max(2, min(round(nrow(mat)/5), 100))), ...)
cluster_by_apcluster(mat, s = apcluster::negDistMat(r = 2), ...)
cluster_by_hdbscan(mat, minPts = 5, ...)
cluster_by_MCL(mat, addLoops = TRUE, ...)
```

#### **Arguments**

mat	A similarity matrix.
method	The clustering methods. Value should be in all_clustering_methods().
control	A list of parameters passed to the corresponding clustering function.
verbose	Whether to print messages.
max_k	Maximal $k$ for k-means/PAM clustering. K-means/PAM clustering is applied from $k = 2$ to $k = max_k$ .
	Other arguments.
minClusterSize	$Minimal\ number\ of\ objects\ in\ a\ cluster.\ Pass\ to\ dynamic {\tt TreeCut::cutreeDynamic()}.$
G	Passed to the G argument in mclust::Mclust() which is the number of clusters.
S	Passed to the s argument in apcluster::apcluster().
minPts	Passed to the minPts argument in dbscan::hdbscan().
addLoops	Passed to the addLoops argument in MCL::mcl().

# **Details**

New clustering methods can be registered by register\_clustering\_methods().

Please note it is better to directly use cluster\_terms() for clustering while not the individual cluster\_by\_\* functions because cluster\_terms() does additional cluster label adjustment.

By default, there are the following clustering methods and corresponding clustering functions:

- kmeans see cluster\_by\_kmeans().
- dynamicTreeCut see cluster\_by\_dynamicTreeCut().
- mclust see cluster\_by\_mclust().
- apcluster see cluster\_by\_apcluster().
- hdbscan see cluster\_by\_hdbscan().
- fast\_greedy see cluster\_by\_fast\_greedy().
- louvain see cluster\_by\_louvain().
- walktrap see cluster\_by\_walktrap().
- MCL see cluster\_by\_MCL().
- binary\_cut see binary\_cut().

cmp\_make\_clusters 7

```
The additional argument in individual clustering functions can be set with the control argument in cluster_terms().
```

cluster\_by\_kmeans(): The best k for k-means clustering is determined according to the "elbow" or "knee" method on the distribution of within-cluster sum of squares (WSS) on each k. All other arguments are passed from  $\dots$  to stats::kmeans().

```
cluster_by_pam(): PAM is applied by fpc::pamk() which can automatically select the best k. All other arguments are passed from ... to fpc::pamk().
```

```
cluster_by_dynamicTreeCut(): All other arguments are passed from ... to dynamicTreeCut::cutreeDynamic().
cluster_by_fast_greedy(): All other arguments are passed from ... to igraph::cluster_fast_greedy().
cluster_by_leading_eigen(): All other arguments are passed from ... to igraph::cluster_leading_eigen().
cluster_by_louvain(): All other arguments are passed from ... to igraph::cluster_louvain().
cluster_by_walktrap(): All other arguments are passed from ... to igraph::cluster_walktrap().
cluster_by_mclust(): All other arguments are passed from ... to mclust::Mclust().
cluster_by_apcluster(): All other arguments are passed from ... to apcluster::apcluster().
cluster_by_hdbscan(): All other arguments are passed from ... to dbscan::hdbscan().
cluster_by_MCL(): All other arguments are passed from ... to MCL::mcl().
```

#### Value

A vector of numeric cluster labels.

cmp\_make\_clusters

Compare clustering methods

### **Description**

Compare clustering methods

```
cmp_make_clusters(
  mat,
  method = setdiff(all_clustering_methods(), "mclust"),
  verbose = TRUE
)

cmp_make_plot(mat, clt, plot_type = c("mixed", "heatmap"), nrow = 3)

compare_clustering_methods(
  mat,
  method = setdiff(all_clustering_methods(), "mclust"),
  plot_type = c("mixed", "heatmap"),
  nrow = 3,
  verbose = TRUE
)
```

8 cmp\_make\_clusters

#### **Arguments**

mat The similarity matrix.

method Which methods to compare. All available methods are in all\_clustering\_methods().

A value of "all" takes all available methods. By default "mclust" is excluded

because its long runtime.

verbose Whether to print messages.

Ddetails The function compares following default clustering methods by default: -kmeans see cluster\_by\_kmeans. -pam see cluster\_by\_pam. -dynamicTreeCut see cluster\_by\_dynamicTreeCut. -mclust see cluster\_by\_mclust. By default it is not included. -apcluster see cluster\_by\_apcluster. -hdbscan see cluster\_by\_hdbscan. -fast\_greedy see cluster\_by\_fast\_greedy. -louvain see cluster\_by\_louvain. -walktrap see cluster\_by\_walktrap. -

MCL see cluster\_by\_MCL.-binary\_cut see binary\_cut.

Also the user-defined methods in all\_clustering\_methods are also compared.

clt A list of clusterings from cmp\_make\_clusters().

plot\_type What type of plots to make. See **Details**.

nrow Number of rows of the layout when plot\_type is set to "heatmap".

#### **Details**

For cmp\_make\_plot(), if plot\_type is the default value "mixed", a figure with three panels will be generated:

- A heatmap of the similarity matrix with different classifications as row annotations.
- A heatmap of the pair-wise concordance of the classifications of every two clustering methods.
- Barplots of the difference scores for each method (calculated by difference\_score), the number of clusters (total clusters and the clusters with size >= 5) and the mean similarity of the terms that are in the same clusters.

If plot\_type is "heatmap". There are heatmaps for the similarity matrix under clusterings from different methods. The last panel is a table with the number of clusters under different clusterings.

compare\_clustering\_methods() is basically a wrapper function of cmp\_make\_clusters() and cmp\_make\_plot().

### Value

```
cmp_make_clusters() returns a list of cluster label vectors from different clustering methods.
cmp_make_plot() returns no value.
compare_clustering_methods() returns no value.
```

count\_words 9

count\_words

Calculate word frequency

### **Description**

Calculate word frequency

### Usage

```
count_words(
   term,
   exclude_words = NULL,
   stop_words = stopwords(),
   min_word_length = 1,
   tokenizer = "words",
   transform_case = tolower,
   remove_numbers = TRUE,
   remove_punctuation = TRUE,
   custom_transformer = NULL,
   stemming = FALSE,
   dictionary = NULL
)
```

# Arguments

term A vector of description texts. exclude\_words The words that should be excluded. The stop words that should be be removed. stop\_words min\_word\_length Minimum length of the word to be counted. The tokenizer function, one of the values accepted by tm::termFreq. tokenizer transform\_case The function normalizing lettercase of the words. remove\_numbers Whether to remove numbers. remove\_punctuation Whether to remove punctuation. custom\_transformer Custom function that transforms words. stemming Whether to only keep the roots of inflected words. dictionary A vector of words to be counted (if given all other words will be excluded).

#### **Details**

The text preprocessing followings the instruction from http://www.sthda.com/english/wiki/word-cloud-generator-in-r-one-killer-function-to-do-everything-you-need.

### Value

A data frame with words and frequencies.

10 dend\_node\_apply

#### **Examples**

```
gm = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
go_id = rownames(gm)
go_term = AnnotationDbi::select(GO.db::GO.db, keys = go_id, columns = "TERM")$TERM
count_words(go_term) |> head()
```

dend\_node\_apply

Apply functions on every node in a dendrogram

### **Description**

Apply functions on every node in a dendrogram

# Usage

```
dend_node_apply(dend, fun)
edit_node(dend, fun = function(d, index) d)
```

### **Arguments**

dend A dendrogram object.

fun A self-defined function.

### **Details**

dend\_node\_apply() returns a vector or a list as the same length as the number of nodes in the dendrogram.

The self-defined function can have one single argument which is the sub-dendrogram at a certain node. E.g. to get the number of members at every node:

```
dend_node_apply(dend, function(d) attr(d, "members"))
```

The self-defined function can have a second argument, which is the index of current sub-dendrogram in the complete dendrogram. E.g. dend[[1]] is the first child node of the complete dendrogram and dend[[c(1, 2)]] is the second child node of dend[[1]], et al. This makes that at a certain node, it is possible to get information of its child nodes and parent nodes.

```
dend_node_apply(dend, function(d, index) {
    dend[[c(index, 1)]] # is the first child node of d, or simply d[[1]]
    dend[[index[-length(index)]]] # is the parent node of d
    ...
})
```

Note for the top node, the value of index is NULL.

In edit\_node(), if fun only has one argument, it is basically the same as stats::dendrapply(), but it can have a second argument which is the index of the node in the dendrogram, which makes it possible to get information of child nodes and parent nodes for a specific node.

As an example, we first assign random values to every node in the dendrogram:

difference\_score 11

```
mat = matrix(rnorm(100), 10)
dend = as.dendrogram(hclust(dist(mat)))
dend = edit_node(dend, function(d) {attr(d, 'score') = runif(1); d})
```

Then for every node, we take the maximal absolute difference to all its child nodes and parent node as the attribute abs\_diff.

```
dend = edit_node(dend, function(d, index) {
   n = length(index)
   s = attr(d, "score")
   if(is.null(index)) { # d is the top node
        s_children = sapply(d, function(x) attr(x, "score"))
        s_parent = NULL
   } else if(is.leaf(d)) { # d is the leaf
        s_{children} = NULL
        s_parent = attr(dend[[index[-n]]], "score")
    } else {
        s_children = sapply(d, function(x) attr(x, "score"))
        s_parent = attr(dend[[index[-n]]], "score")
   abs_diff = max(abs(s - c(s_children, s_parent)))
   attr(d, "abs_diff") = abs_diff
   return(d)
})
```

### Value

dend\_node\_apply() returns a vector or a list, depends on whether fun returns a scalar or more complex values.

edit\_node() returns a dendrogram object.

### **Examples**

```
mat = matrix(rnorm(100), 10)
dend = as.dendrogram(hclust(dist(mat)))
# number of members on every node
dend_node_apply(dend, function(d) attr(d, "members"))
# the depth on every node
dend_node_apply(dend, function(d, index) length(index))
```

difference\_score

Difference score

# Description

Difference score

```
difference_score(mat, cl)
```

12 export\_to\_shiny\_app

#### **Arguments**

mat The similarity matrix.

cl Cluster labels.

### **Details**

This function measures the different between the similarity values for the terms that belong to the same clusters and in different clusters. The difference score is the Kolmogorov-Smirnov statistic between the two distributions.

### Value

A numeric scalar.

### **Examples**

export\_to\_shiny\_app

Interactively visualize the similarity heatmap

# **Description**

Interactively visualize the similarity heatmap

### Usage

```
export_to_shiny_app(mat, cl = binary_cut(mat))
```

# **Arguments**

mat A similarity matrix.

cl Cluster labels inferred from the similarity matrix, e.g. from cluster\_terms() or binary\_cut().

•

### Value

A shiny application.

GO\_similarity 13

00 1 13 11	$\alpha$ 1 1 $\alpha$	0 1 /00	
GO_similarity	Calculate Gene	Ontology (GO)	) semantic similarity matrix

# Description

Calculate Gene Ontology (GO) semantic similarity matrix

# Usage

```
GO_similarity(
   go_id,
   ont = NULL,
   db = "org.Hs.eg.db",
   measure = "Sim_XGraSM_2013"
)
guess_ont(go_id, db = "org.Hs.eg.db")
random_GO(n, ont = c("BP", "CC", "MF"), db = "org.Hs.eg.db")
```

# **Arguments**

go_id	A vector of GO IDs.
ont	Sub-ontology of GO. Value should be one of "BP", "CC" or "MF". If it is not specified, the function automatically identifies it by random sampling 10 IDs from go_id (see guess_ont()).
db	Annotation database. It should be an OrgDb package name from https://bioconductor.org/packages/release/BiocViews.html#OrgDb. The value can also directly be an OrgDb object.
measure	Semantic measure for the GO similarity, pass to simona::term_sim(). All valid values are in simona::all_term_sim_methods().
n	Number of GO IDs

# **Details**

The default similarity method is "Sim\_XGraSM\_2013". Since the semantic similarities are calculated based on gene annotations to GO terms, I suggest users also try the following methods:

```
"Sim_Lin_1998"
"Sim_Resnik_1999"
"Sim_Relevance_2006"
"Sim_SimIC_2010"
"Sim_XGraSM_2013"
"Sim_EISI_2015"
"Sim_AIC_2014"
"Sim_Wang_2007"
```

• "Sim\_GOGO\_2018"

In guess\_ont(), only 10 random GO IDs are checked.

In random\_GO(), only GO terms with gene annotations are sampled.

14 ht\_clusters

### Value

```
{\tt GO\_similarity()}\ returns\ a\ symmetric\ matrix.
```

 ${\tt guess\_ont()} \ \ {\tt returns} \ \ {\tt a} \ \ {\tt single} \ \ {\tt character} \ \ {\tt scalar} \ \ {\tt of} \ "BP", "CC" \ \ {\tt or} \ "MF". \ \ {\tt If} \ \ {\tt there} \ \ {\tt are} \ \ {\tt more} \ \ {\tt than} \ \ {\tt one} \ \ {\tt ontologies} \ \ {\tt detected}. \ \ {\tt It} \ \ {\tt returns} \ \ {\tt NULL}.$ 

random\_GO() returns a vector of GO IDs.

# **Examples**

```
go_id = random_GO(100)
mat = GO_similarity(go_id)

go_id = random_GO(100)
guess_ont(go_id)
```

ht\_clusters

Visualize the similarity matrix and the clustering

# **Description**

Visualize the similarity matrix and the clustering

```
ht_clusters(
  mat,
  cl,
  dend = NULL,

ht\_clusters 15

# **Arguments**

mat	A similarity matrix.
cl	Cluster labels inferred from the similarity matrix, e.g. from cluster_terms() or binary_cut().
dend	Used internally.
col	A vector of colors that map from 0 to the 97.5 <sup>th</sup> percentile of the similarity values. The value can also be a color mapping function generated by circlize::colorRamp2().
draw_word_cloud	l
	Whether to draw the word clouds.
min_term	Minimal number of functional terms in a cluster. All the clusters with size less than min_term are all merged into one separated cluster in the heatmap.
order_by_size	Whether to reorder clusters by their sizes. The cluster that is merged from small clusters (size < min_term) is always put to the bottom of the heatmap.
stat	Type of value for mapping to the font size of keywords in the word clouds. There are two options: "count": simply number of keywords; "pvalue": enrichment on keywords is performed (by fisher's exact test) and -log10(pvalue) is used to map to font sizes.
min_stat	Minimal value for stat for selecting keywords.
exclude_words	Words that are excluded in the word cloud.
max_words	Maximal number of words visualized in the word cloud.
word_cloud_grob	·
	A list of graphic parameters passed to word_cloud_grob().
fontsize_range	The range of the font size. The value should be a numeric vector with length two. The font size interpolation is linear.
bg_gp	Graphics parameters for controlling word cloud annotation background.
column_title	Column title for the heatmap.
ht_list	A list of additional heatmaps added to the left of the similarity heatmap.
use_raster	Whether to write the heatmap as a raster image.
run_draw	Internally used.
	$Other\ arguments\ passed\ to\ {\tt ComplexHeatmap::draw,HeatmapList-method}.$

# Value

 $A \ {\tt ComplexHeatmap::HeatmapList} \ object.$ 

```
\begin{tabular}{ll} keyword\_enrichment\_from\_GO \\ \hline \textit{Keyword enrichment for GO terms} \end{tabular}
```

# Description

Keyword enrichment for GO terms

# Usage

```
keyword_enrichment_from_GO(go_id, min_bg = 5, min_term = 2)
```

# **Arguments**

go_id	A vector of GO IDs.
min_bg	Minimal number of GO terms (in the background, i.e. all GO temrs in the GO database) that contain a specific keyword.
min_term	Minimal number of GO terms (GO terms in go_id) that contain a specific keyword.

# **Details**

The enrichment is applied by Fisher's exact test. For a keyword, there is the following 2x2 contigency table:

	contains	the keyword		does	not	contain	the	keyword
In the GO set	l	s11				s12		
Not in the GO set	I	s21	Ι			s22		

where s11, s12, s21 and s22 are the counts of GO terms in the four categories.

# Value

A data frame with keyword enrichment results.

```
go_id = random_GO(100)
keyword_enrichment_from_GO(go_id)
```

partition\_by\_kmeans 17

# **Description**

Partition the matrix

### Usage

```
partition_by_kmeans(mat, n_repeats = 10)
partition_by_pam(mat)
partition_by_hclust(mat)
partition_by_kmeanspp(mat)
```

### **Arguments**

mat The submatrix in the binary cut clustering process.

n\_repeats Number of repeated runs of k-means clustering.

### **Details**

These functions can be set to the partition\_fun argument in binary\_cut().

partition\_by\_kmeans(): Since k-means clustering brings randomness, this function performs k-means clustering several times (controlled by n\_repeats) and uses the final consensus partitioning results.

partition\_by\_pam(): The clustering is performed by cluster::pam() with the pamonce argument set to 5.

partition\_by\_hclust(): The "ward.D2" clusering method was used.

partition\_by\_kmeanspp(): It uses the kmeanspp method from the **flexclust** package.

# Value

All partitioning functions split the matrix into two groups and return a categorical vector of labels of 1 and 2.

plot\_binary\_cut Cluster functional terms by recursively binary cutting the similarity matrix

# Description

Cluster functional terms by recursively binary cutting the similarity matrix

18 plot\_binary\_cut

#### Usage

```
plot_binary_cut(
  mat,
  value_fun = area_above_ecdf,
  cutoff = 0.85,
  partition_fun = partition_by_pam,
  dend = NULL,
  dend_width = unit(3, "cm"),
  depth = NULL,
  show_heatmap_legend = TRUE,
)
binary_cut(
  mat,
  value_fun = area_above_ecdf,
  partition_fun = partition_by_hclust,
  cutoff = 0.85,
  try_all_partition_fun = TRUE,
  partial = nrow(mat) > 1500
```

# **Arguments**

mat A similarity matrix.

value\_fun A function that calculates the scores for the four submatrices on a node.

cutoff The cutoff for splitting the dendrogram.

partition\_fun A function to split each node into two groups. Pre-defined functions in this pack-

age are partition\_by\_kmeanspp(), partition\_by\_pam() and partition\_by\_hclust().

dend A dendrogram object, used internally.

dend\_width Width of the dendrogram on the plot.

depth Depth of the recursive binary cut process.

 $\verb|show_heatmap_legend|$ 

Whether to show the heatmap legend.

.. Other arguments.

try\_all\_partition\_fun

Different partition\_fun may give different clusterings. If the vaule of try\_all\_partition\_fun is set to TRUE, the similarity matrix is clustered by three partitioning method: partition\_by\_pam(), partition\_by\_kmeanspp() and partition\_by\_hclust(). The clustering with the highest difference score is finally selected as the final

clustering.

partial Whether to generate the complete clustering or the clustering stops when sub-

matrices cannot be split anymore.

### **Details**

After the functions which perform clustering are executed, such as simplifyGO() or binary\_cut(), the dendrogram is temporarily saved and plot\_binary\_cut() directly uses this dendrogram.

#### Value

binary\_cut() returns a vector of numeric cluster labels.

# **Examples**

 ${\tt register\_clustering\_methods}$ 

Configure clustering methods

### **Description**

Configure clustering methods

# Usage

```
register_clustering_methods(...)
all_clustering_methods()
remove_clustering_methods(method)
reset_clustering_methods()
```

# **Arguments**

... A named list of clustering functions, see in **Details**.

method A vector of method names.

#### Details

The user-defined functions should accept at least one argument which is the input matrix. The second optional argument should always be ... so that parameters for the clustering function can be passed by the control argument from cluster\_terms(), simplifyGO() or simplifyEnrichment(). If users forget to add ..., it is added internally.

Please note, the user-defined function should automatically identify the optimized number of clusters

The function should return a vector of cluster labels. Internally it is converted to numeric labels.

The default clustering methods are:

• kmeans see cluster\_by\_kmeans().

20 scale\_fontsize

```
• dynamicTreeCut see cluster_by_dynamicTreeCut().
```

- mclust see cluster\_by\_mclust().
- apcluster see cluster\_by\_apcluster().
- hdbscan see cluster\_by\_hdbscan().
- fast\_greedy see cluster\_by\_fast\_greedy().
- louvain see cluster\_by\_louvain().
- walktrap see cluster\_by\_walktrap().
- MCL see cluster\_by\_MCL().
- binary\_cut see binary\_cut().

### Value

all\_clustering\_methods() returns a vector of clustering method names.

# **Examples**

```
register_clustering_methods(
    # assume there are 5 groups
    random = function(mat, ...) sample(5, nrow(mat), replace = TRUE)
)
all_clustering_methods()
remove_clustering_methods()
remove_clustering_methods()
remove_clustering_methods(c("kmeans", "mclust"))
all_clustering_methods()
reset_clustering_methods()
all_clustering_methods()
```

scale\_fontsize

Scale font size

### **Description**

Scale font size

# Usage

```
scale_fontsize(x, rg = c(1, 30), fs = c(4, 16))
```

# **Arguments**

x A numeric vector.

rg The range.

fs Range of the font size.

# Details

It is a linear interpolation.

select\_cutoff 21

#### Value

A numeric vector.

# **Examples**

```
x = runif(10, min = 1, max = 20)
# scale x to fontsize 4 to 16.
scale_fontsize(x)
```

select\_cutoff

Select the cutoff for binary cut

# **Description**

Select the cutoff for binary cut

# Usage

```
select_cutoff(
  mat,
  cutoff = seq(0.6, 0.98, by = 0.01),
  verbose = se_opt$verbose,
  ...
)
```

# Arguments

```
mat A similarity matrix.

cutoff A list of cutoffs to test. Note the range of the cutoff values should be inside [0.5, 1].

verbose Whether to print messages.

Pass to binary_cut().
```

# **Details**

Binary cut is applied to each cutoff and the clustering results are evaluated by following metrics:

- difference score, calculated by difference\_score().
- · number of clusters.
- block mean, which is the mean similarity in the blocks in the diagonal of the heatmap.

22 simplifyGO

se\_opt

Global parameters

# Description

Global parameters

# Usage

```
se_opt(..., RESET = FALSE, READ.ONLY = NULL, LOCAL = FALSE, ADD = FALSE)
```

# **Arguments**

... Arguments for the parameters, see "details" section.

RESET Whether to reset to default values.

READ.ONLY Please ignore.

LOCAL Please ignore.

ADD Please ignore.

### **Details**

There are the following global options:

• verobse: Whether to print messages.

# Value

A GlobalOptionsFun object.

simplifyG0

Simplify Gene Ontology (GO) enrichment results

# Description

Simplify Gene Ontology (GO) enrichment results

```
simplifyGO(
  mat,
  method = "binary_cut",
  control = list(),
  plot = TRUE,
  verbose = TRUE,
  column_title = qq("@{nrow(mat)} GO terms clustered by '@{method}'"),
  ht_list = NULL,
  ...
)
simplifyEnrichment(...)
```

simplifyGO 23

### **Arguments**

mat	A GO similarity matrix. You can also provide a vector of GO IDs to this argument.
method	Method for clustering the matrix. See cluster_terms().
control	A list of parameters for controlling the clustering method, passed to ${\tt cluster\_terms()}$ .
plot	Whether to make the heatmap.
verbose	Whether to print messages.
column_title	Column title for the heatmap.
ht_list	A list of additional heatmaps added to the left of the similarity heatmap.
	Arguments passed to ht_clusters().

### **Details**

This is basically a wrapper function that it first runs cluster\_terms() to cluster GO terms and then runs ht\_clusters() to visualize the clustering.

The arguments in simplifyGO() passed to ht\_clusters() are:

- draw\_word\_cloud: Whether to draw the word clouds.
- min\_term: Minimal number of GO terms in a cluster. All the clusters with size less than min\_term are all merged into one single cluster in the heatmap.
- order\_by\_size: Whether to reorder GO clusters by their sizes. The cluster that is merged from small clusters (size < min\_term) is always put to the bottom of the heatmap.
- stat: What values of keywords are used to map to font sizes in the word clouds.
- exclude\_words: Words that are excluded in the word cloud.
- max\_words: Maximal number of words visualized in the word cloud.
- word\_cloud\_grob\_param: A list of graphic parameters passed to word\_cloud\_grob().
- fontsize\_range The range of the font size. The value should be a numeric vector with length two. The minimal font size is mapped to word frequency value of 1 and the maximal font size is mapped to the maximal word frequency. The font size interlopation is linear.
- bg\_gp: Graphic parameters for controlling the background of word cloud annotations.

# Value

A data frame with two columns: GO IDs and cluster labels.

```
set.seed(123)
go_id = random_GO(500)
mat = GO_similarity(go_id)
df = simplifyGO(mat, word_cloud_grob_param = list(max_width = 80))
head(df)
```

```
simplifyGOFromMultipleLists
```

Perform simplifyGO analysis with multiple lists of GO IDs

# Description

Perform simplifyGO analysis with multiple lists of GO IDs

# Usage

```
simplifyGOFromMultipleLists(
  go_id_column = NULL,
  padj_column = NULL,
  padj_cutoff = 0.01,
  filter = function(x) any(x < padj_cutoff),</pre>
  default = 1,
  ont = NULL,
  db = "org.Hs.eg.db",
  measure = "Sim_XGraSM_2013",
  heatmap_param = list(NULL),
  show_barplot = TRUE,
  method = "binary_cut",
  control = list(),
  min_term = NULL,
  verbose = TRUE,
  column_title = NULL,
)
```

### **Arguments**

lt	A data frame, a list of numeric vectors (e.g. adjusted p-values) where each numeric vector has GO IDs as names, or a list of GO IDs.
go_id_column	Column index of GO ID if 1t contains a list of data frames.
padj_column	Column index of adjusted p-values if 1t contains a list of data frames.
padj_cutoff	Cut off for adjusted p-values.
filter	A self-defined function for filtering GO IDs. By default it requires GO IDs should be significant in at least one list.
default	The default value for the adjusted p-values. See <b>Details</b> .
ont	Pass to GO_similarity().
db	Pass to GO_similarity().
measure	Pass to GO_similarity().
heatmap_param	Parameters for controlling the heatmap, see <b>Details</b> .
show_barplot	Whether draw barplots which shows numbers of significant GO terms in clusters.
method	Pass to simplifyGO().

```
control Pass to simplifyGO().
min_term Pass to simplifyGO().
verbose Pass to simplifyGO().
column_title Pass to simplifyGO().
... Pass to simplifyGO().
```

### **Details**

The input data can have three types of formats:

- A list of numeric vectors of adjusted p-values where each vector has the GO IDs as names.
- A data frame. The column of the GO IDs can be specified with go\_id\_column argument and the column of the adjusted p-values can be specified with padj\_column argument. If these columns are not specified, they are automatically identified. The GO ID column is found by checking whether a column contains all GO IDs. The adjusted p-value column is found by comparing the column names of the data frame to see whether it might be a column for adjusted p-values. These two columns are used to construct a numeric vector with GO IDs as names.
- A list of character vectors of GO IDs. In this case, each character vector is changed to a numeric vector where all values take 1 and the original GO IDs are used as names of the vector

Now let's assume there are n GO lists, we first construct a global matrix where columns correspond to the n GO lists and rows correspond to the "union" of all GO IDs in the lists. The value for the ith GO ID and in the jth list are taken from the corresponding numeric vector in 1t. If the jth vector in 1t does not contain the ith GO ID, the value defined by default argument is taken there (e.g. in most cases the numeric values are adjusted p-values, default is set to 1). Let's call this matrix as M0.

Next step is to filter M0 so that we only take a subset of GO IDs of interest. We define a proper function via argument filter to remove GO IDs that are not important for the analysis. Functions for filter is applied to every row in M0 and filter function needs to return a logical value to decide whether to remove the current GO ID. For example, if the values in lt are adjusted p-values, the filter function can be set as function(x) any(x < padj\_cutoff) so that the GO ID is kept as long as it is signflicant in at least one list. After the filter, let's call the filtered matrix M1.

GO IDs in M1 (row names of M1) are used for clustering. A heatmap of M1 is attached to the left of the GO similarity heatmap so that the group-specific (or list-specific) patterns can be easily observed and to corresponded to GO functions.

Argument heatmap\_param controls several parameters for heatmap M1:

- transform: A self-defined function to transform the data for heatmap visualization. The most typical case is to transform adjusted p-values by -log10(x).
- breaks: break values for color interpolation.
- col: The corresponding values for breaks.
- labels: The corresponding labels.
- name: Legend title.

26 summarizeGO

#### **Examples**

```
# perform functional enrichment on the signatures genes from cola anlaysis
require(cola)
data(golub_cola)
res = golub_cola["ATC:skmeans"]
require(hu6800.db)
x = hu6800ENTREZID
mapped_probes = mappedkeys(x)
id_mapping = unlist(as.list(x[mapped_probes]))
lt = functional_enrichment(res, k = 3, id_mapping = id_mapping) # you can check the value of `lt`
# a list of data frames
simplifyGOFromMultipleLists(lt, padj_cutoff = 0.001)
# a list of numeric values
lt2 = lapply(lt, function(x) structure(x$p.adjust, names = x$ID))
simplifyGOFromMultipleLists(lt2, padj_cutoff = 0.001)
# a list of GO IDS
lt3 = lapply(lt, function(x) x$ID[x$p.adjust < 0.001])</pre>
simplifyGOFromMultipleLists(1t3)
```

summarizeG0

A simplified way to visualize enrichment in GO clusters

# Description

A simplified way to visualize enrichment in GO clusters

```
summarizeGO(
 go_id,
 value = NULL,
  aggregate = mean,
 method = "binary_cut",
 control = list(),
 verbose = TRUE,
  axis_label = "Value",
  title = "",
 legend_title = axis_label,
 min_term = round(nrow(mat) * 0.01),
 stat = "pvalue",
 min_stat = ifelse(stat == "count", 5, 0.05),
 exclude_words = character(0),
 max\_words = 6,
 word_cloud_grob_param = list(),
  fontsize_range = c(4, 16),
 bg_gp = gpar(fill = "#DDDDDD", col = "#AAAAAA")
```

word\_cloud\_grob 27

### **Arguments**

go\_id A vector of GO IDs.

value A list of numeric value associate with go\_id. We suggest to use -log10(p.adjust)

or -log2(fold enrichment) as the values.

aggregate Function to aggregate values in each GO cluster.

method Method for clustering the matrix. See cluster\_terms().

control A list of parameters for controlling the clustering method, passed to cluster\_terms().

verbose Whether to print messages.

axis\_label X-axis label.

title Title for the whole plot. legend\_title Title for the legend.

min\_term Minimal number of functional terms in a cluster. All the clusters with size less

than min\_term are all merged into one separated cluster in the heatmap.

stat Type of value for mapping to the font size of keywords in the word clouds. There

are two options: "count": simply number of keywords; "pvalue": enrichment on keywords is performed (by fisher's exact test) and -log10(pvalue) is used to map

to font sizes.

min\_stat Minimal value for stat for selecting keywords.

exclude\_words Words that are excluded in the word cloud.

max\_words Maximal number of words visualized in the word cloud.

word\_cloud\_grob\_param

A list of graphic parameters passed to word\_cloud\_grob.

fontsize\_range The range of the font size. The value should be a numeric vector with length

two. The font size interpolation is linear.

bg\_gp Graphics parameters for controlling word cloud annotation background.

### **Details**

There are several other ways to specify GO IDs and the associated values.

- 1. specify value as a named vector where GO IDs are the names.
- 2. specify value as a list of numeric named vectors. In this case, value contains multiple enrichment results.

Please refer to https://jokergoo.github.io/2023/10/02/simplified-simplifyenrichment-plot/for more examples of this function.

word\_cloud\_grob A simple grob for the word cloud

# Description

A simple grob for the word cloud

28 word\_cloud\_grob

#### Usage

```
word_cloud_grob(
   text,
   fontsize,
   line_space = unit(4, "pt"),
   word_space = unit(80, "mm"),
   col = function(fs) circlize::rand_color(length(fs), luminosity = "dark"),
   add_new_line = FALSE,
   test = FALSE
)

## S3 method for class 'word_cloud'
widthDetails(x)

## S3 method for class 'word_cloud'
heightDetails(x)
```

# **Arguments** text

text	A vector of words.
fontsize	The corresponding font size. With the frequency of the words known, scale_fontsize can be used to linearly interpolate frequencies to font sizes.
line_space	Space between lines. The value can be a grid::unit object or a numeric scalar which is measured in mm.
word_space	Space between words. The value can be a grid::unit object or a numeric scalar which is measured in mm.
max_width	The maximal width of the viewport to put the word cloud. The value can be a grid::unit object or a numeric scalar which is measured in mm. Note this might be larger than the final width of the returned grob object.
col	Colors for the words. The value can be a vector, in numeric or character, which should have the same length as text. Or it is a self-defined function that takes the font size vector as the only argument. The function should return a color vector. See Examples.
add_new_line	Whether to add new line after every word? If TRUE, each word will be in a separated line.
test	Internally used. It basically adds borders to the words and the viewport.

# Value

Х

A grid::grob object. The width and height of the grob can be get by grid::grobWidth and grid::grobHeight.

The word\_cloud grob returned by word\_cloud\_grob.

```
# very old R versions do not have strrep() function
if(!exists("strrep")) {
    strrep = function(x, i) paste(rep(x, i), collapse = "")
}
words = sapply(1:30, function(x) strrep(sample(letters, 1), sample(3:10, 1)))
```

word\_cloud\_grob 29

```
require(grid)
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
   max_width = 100)
grid.newpage(); grid.draw(gb)
# color as a single scalar
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
   max_width = 100, col = 1)
grid.newpage(); grid.draw(gb)
# color as a vector
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
   max_width = 100, col = 1:30)
grid.newpage(); grid.draw(gb)
# color as a function
require(circlize)
col_fun = colorRamp2(c(5, 17, 30), c("blue", "black", "red"))
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
    max_width = 100, col = function(fs) col_fun(fs))
grid.newpage(); grid.draw(gb)
```
