

Package ‘tfestimators’

August 19, 2025

Type Package

Title Interface to 'TensorFlow' Estimators

Version 1.9.3

Description Interface to 'TensorFlow' Estimators

<<https://www.tensorflow.org/guide/estimator>>, a high-level API that provides implementations of many different model types including linear models and deep neural networks.

boosted_trees_estimators	
<i>Boosted Trees Estimator</i>	

Description

Construct a boosted trees estimator.

Usage

```
boosted_trees_regressor(  
  feature_columns,  
  n_batches_per_layer,  
  model_dir = NULL,  
  label_dimension = 1L,  
  weight_column = NULL,  
  n_trees = 100L,  
  max_depth = 6L,  
  learning_rate = 0.1,  
  l1_regularization = 0,  
  l2_regularization = 0,  
  tree_complexity = 0,  
  min_node_weight = 0,  
  config = NULL  
)  
  
boosted_trees_classifier(  
  feature_columns,  
  n_batches_per_layer,  
  model_dir = NULL,  
  n_classes = 2L,  
  weight_column = NULL,  
  label_vocabulary = NULL,  
  n_trees = 100L,
```

```

    max_depth = 6L,
    learning_rate = 0.1,
    l1_regularization = 0,
    l2_regularization = 0,
    tree_complexity = 0,
    min_node_weight = 0,
    config = NULL
  )

```

Arguments

<code>feature_columns</code>	An R list containing all of the feature columns used by the model (typically, generated by <code>feature_columns()</code>).
<code>n_batches_per_layer</code>	The number of batches to collect statistics per layer.
<code>model_dir</code>	Directory to save the model parameters, graph, and so on. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model.
<code>label_dimension</code>	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
<code>weight_column</code>	A string, or a numeric column created by <code>column_numeric()</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the <code>features</code> argument. If it is a numeric column, then the raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.
<code>n_trees</code>	Number trees to be created.
<code>max_depth</code>	Maximum depth of the tree to grow.
<code>learning_rate</code>	Shrinkage parameter to be used when a tree added to the model.
<code>l1_regularization</code>	Regularization multiplier applied to the absolute weights of the tree leafs.
<code>l2_regularization</code>	Regularization multiplier applied to the square weights of the tree leafs.
<code>tree_complexity</code>	Regularization factor to penalize trees with more leaves.
<code>min_node_weight</code>	Minimum hessian a node must have for a split to be considered. The value will be compared with <code>sum(leaf_hessian)/(batch_size * n_batches_per_layer)</code> .
<code>config</code>	A run configuration created by <code>run_config()</code> , used to configure the runtime settings.
<code>n_classes</code>	The number of label classes.
<code>label_vocabulary</code>	A list of strings represents possible label values. If given, labels must be string type and have any value in <code>label_vocabulary</code> . If it is not given, that means

labels are already encoded as integer or float within $[0, 1]$ for `n_classes == 2` and encoded as integer values in $\{0, 1, \dots, n_classes - 1\}$ for `n_classes > 2`. Also there will be errors if vocabulary is not provided and labels are string.

classifier_parse_example_spec

Generates Parsing Spec for TensorFlow Example to be Used with Classifiers

Description

If users keep data in TensorFlow Example format, they need to call `tf$parse_example` with a proper feature spec. There are two main things that this utility helps:

- Users need to combine parsing spec of features with labels and weights (if any) since they are all parsed from same `tf$Example` instance. This utility combines these specs.
- It is difficult to map expected label by a classifier such as `dnn_classifier` to corresponding `tf$parse_example` spec. This utility encodes it by getting related information from users (key, dtype).

Usage

```
classifier_parse_example_spec(
  feature_columns,
  label_key,
  label_dtype = tf$int64,
  label_default = NULL,
  weight_column = NULL
)
```

Arguments

<code>feature_columns</code>	An iterable containing all feature columns. All items should be instances of classes derived from <code>_FeatureColumn</code> .
<code>label_key</code>	A string identifying the label. It means <code>tf\$Example</code> stores labels with this key.
<code>label_dtype</code>	A <code>tf\$dtype</code> identifies the type of labels. By default it is <code>tf\$int64</code> . If user defines a <code>label_vocabulary</code> , this should be set as <code>tf\$string</code> . <code>tf\$float32</code> labels are only supported for binary classification.

- label_default** used as label if label_key does not exist in given `tf$Example`. An example usage: let's say label_key is 'clicked' and `tf$Example` contains clicked data only for positive examples in following format `key:clicked, value:1`. This means that if there is no data with key 'clicked' it should count as negative example by setting `label_default=0`. Type of this value should be compatible with `label_dtype`.
- weight_column** A string or a numeric column created by `column_numeric()` defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the features. If it is a numeric column, raw tensor is fetched by key `weight_column$key`, then `weight_column$normalizer_fn` is applied on it to get weight tensor.

Value

A dict mapping each feature key to a `FixedLenFeature` or `VarLenFeature` value.

Raises

- `ValueError`: If label is used in `feature_columns`.
- `ValueError`: If `weight_column` is used in `feature_columns`.
- `ValueError`: If any of the given `feature_columns` is not a feature column instance.
- `ValueError`: If `weight_column` is not a numeric column instance.
- `ValueError`: if `label_key` is `NULL`.

See Also

Other parsing utilities: `regressor_parse_example_spec()`

column-scope

Establish a Feature Columns Selection Scope

Description

This helper function provides a set of names to be used by `tidyselect` helpers in e.g. `feature_columns()`.

Usage

```
set_columns(columns)
```

```
with_columns(columns, expr)
```

```
scoped_columns(columns)
```

Arguments

columns	Either a named R object (whose names will be used to provide a selection context), or a character vector of such names.
expr	An R expression, to be evaluated with the selection context active.

column_base	<i>Base Documentation for Feature Column Constructors</i>
-------------	---

Description

Base Documentation for Feature Column Constructors

Arguments

...	Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.
-----	---

column_bucketized	<i>Construct a Bucketized Column</i>
-------------------	--------------------------------------

Description

Construct a bucketized column, representing discretized dense input. Buckets include the left boundary, and exclude the right boundary.

Usage

```
column_bucketized(source_column, boundaries)
```

Arguments

source_column	A one-dimensional dense column, as generated by column_numeric() .
boundaries	A sorted list or list of floats specifying the boundaries.

Value

A bucketized column.

Raises

- ValueError: If source_column is not a numeric column, or if it is not one-dimensional.
- ValueError: If boundaries is not a sorted list or list.

See Also

Other feature column constructors: [column_categorical_weighted\(\)](#), [column_categorical_with_hash_bucket\(\)](#), [column_categorical_with_identity\(\)](#), [column_categorical_with_vocabulary_file\(\)](#), [column_categorical_with_dictionary_file\(\)](#), [column_crossed\(\)](#), [column_embedding\(\)](#), [column_numeric\(\)](#), [input_layer\(\)](#)

`column_categorical_weighted`*Construct a Weighted Categorical Column*

Description

Use this when each of your sparse inputs has both an ID and a value. For example, if you're representing text documents as a collection of word frequencies, you can provide 2 parallel sparse input features ('terms' and 'frequencies' below).

Usage

```
column_categorical_weighted(  
    categorical_column,  
    weight_feature_key,  
    dtype = tf$float32  
)
```

Arguments

<code>categorical_column</code>	A categorical column created by <code>column_categorical_*</code> () functions.
<code>weight_feature_key</code>	String key for weight values.
<code>dtype</code>	Type of weights, such as <code>tf\$float32</code> . Only float and integer weights are supported.

Value

A categorical column composed of two sparse features: one represents id, the other represents weight (value) of the id feature in that example.

Raises

- `ValueError`: if `dtype` is not convertible to float.

See Also

Other feature column constructors: [column_bucketized\(\)](#), [column_categorical_with_hash_bucket\(\)](#), [column_categorical_with_identity\(\)](#), [column_categorical_with_vocabulary_file\(\)](#), [column_categorical_with_column_crossed\(\)](#), [column_embedding\(\)](#), [column_numeric\(\)](#), [input_layer\(\)](#)

column_categorical_with_hash_bucket

Represents Sparse Feature where IDs are set by Hashing

Description

Use this when your sparse features are in string or integer format, and you want to distribute your inputs into a finite number of buckets by hashing. `output_id = Hash(input_feature_string) % bucket_size` For input dictionary features, `features$key$` is either tensor or sparse tensor object. If it's tensor object, missing values can be represented by `-1` for int and `' '` for string. Note that these values are independent of the `default_value` argument.

Usage

```
column_categorical_with_hash_bucket(..., hash_bucket_size, dtype = tf$string)
```

Arguments

`...` Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.

`hash_bucket_size` An int > 1. The number of buckets.

`dtype` The type of features. Only string and integer types are supported.

Value

A `_HashedCategoricalColumn`.

Raises

- `ValueError`: `hash_bucket_size` is not greater than 1.
- `ValueError`: `dtype` is neither string nor integer.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_file()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_embedding()`, `column_numeric()`, `input_layer()`

column_categorical_with_identity

Construct a Categorical Column that Returns Identity Values

Description

Use this when your inputs are integers in the range $[0, \text{num_buckets})$, and you want to use the input value itself as the categorical ID. Values outside this range will result in `default_value` if specified, otherwise it will fail.

Usage

```
column_categorical_with_identity(..., num_buckets, default_value = NULL)
```

Arguments

<code>...</code>	Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.
<code>num_buckets</code>	Number of unique values.
<code>default_value</code>	If NULL, this column's graph operations will fail for out-of-range inputs. Otherwise, this value must be in the range $[0, \text{num_buckets})$, and will replace inputs in that range.

Details

Typically, this is used for contiguous ranges of integer indexes, but it doesn't have to be. This might be inefficient, however, if many of IDs are unused. Consider `column_categorical_with_hash_bucket()` in that case.

For input dictionary features, `features$key` is either tensor or sparse tensor object. If it's tensor object, missing values can be represented by `-1` for int and `' '` for string. Note that these values are independent of the `default_value` argument.

Value

A categorical column that returns identity values.

Raises

- `ValueError`: if `num_buckets` is less than one.
- `ValueError`: if `default_value` is not in range $[0, \text{num_buckets})$.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_vocabulary_file()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_embedding()`, `column_numeric()`, `input_layer()`

column_categorical_with_vocabulary_file

Construct a Categorical Column with a Vocabulary File

Description

Use this when your inputs are in string or integer format, and you have a vocabulary file that maps each value to an integer ID. By default, out-of-vocabulary values are ignored. Use either (but not both) of `num_oov_buckets` and `default_value` to specify how to include out-of-vocabulary values. For input dictionary features, `features[key]` is either tensor or sparse tensor object. If it's tensor object, missing values can be represented by `-1` for int and `' '` for string. Note that these values are independent of the `default_value` argument.

Usage

```
column_categorical_with_vocabulary_file(
    ...,
    vocabulary_file,
    vocabulary_size,
    num_oov_buckets = 0L,
    default_value = NULL,
    dtype = tf$string
)
```

Arguments

<code>...</code>	Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.
<code>vocabulary_file</code>	The vocabulary file name.
<code>vocabulary_size</code>	Number of the elements in the vocabulary. This must be no greater than length of <code>vocabulary_file</code> , if less than length, later values are ignored.
<code>num_oov_buckets</code>	Non-negative integer, the number of out-of-vocabulary buckets. All out-of-vocabulary inputs will be assigned IDs in the range <code>[vocabulary_size, vocabulary_size+num_oov_buckets]</code> based on a hash of the input value. A positive <code>num_oov_buckets</code> can not be specified with <code>default_value</code> .
<code>default_value</code>	The integer ID value to return for out-of-vocabulary feature values, defaults to <code>-1</code> . This can not be specified with a positive <code>num_oov_buckets</code> .
<code>dtype</code>	The type of features. Only string and integer types are supported.

Value

A categorical column with a vocabulary file.

Raises

- `ValueError`: `vocabulary_file` is missing.
- `ValueError`: `vocabulary_size` is missing or < 1 .
- `ValueError`: `num_oov_buckets` is not a non-negative integer.
- `ValueError`: `dtype` is neither string nor integer.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_embedding()`, `column_numeric()`, `input_layer()`

`column_categorical_with_vocabulary_list`

Construct a Categorical Column with In-Memory Vocabulary

Description

Use this when your inputs are in string or integer format, and you have an in-memory vocabulary mapping each value to an integer ID. By default, out-of-vocabulary values are ignored. Use `default_value` to specify how to include out-of-vocabulary values. For the input dictionary features, `features$key` is either tensor or sparse tensor object. If it's tensor object, missing values can be represented by `-1` for int and `' '` for string.

Usage

```
column_categorical_with_vocabulary_list(
    ...,
    vocabulary_list,
    dtype = NULL,
    default_value = -1L,
    num_oov_buckets = 0L
)
```

Arguments

<code>...</code>	Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.
<code>vocabulary_list</code>	An ordered iterable defining the vocabulary. Each feature is mapped to the index of its value (if present) in <code>vocabulary_list</code> . Must be castable to <code>dtype</code> .
<code>dtype</code>	The type of features. Only string and integer types are supported. If <code>NULL</code> , it will be inferred from <code>vocabulary_list</code> .
<code>default_value</code>	The value to use for values not in <code>vocabulary_list</code> .

num_oov_buckets

Non-negative integer, the number of out-of-vocabulary buckets. All out-of-vocabulary inputs will be assigned IDs in the range [vocabulary_size, vocabulary_size+num_oov_buckets) based on a hash of the input value. A positive num_oov_buckets can not be specified with default_value.

Details

Note that these values are independent of the default_value argument.

Value

A categorical column with in-memory vocabulary.

Raises

- ValueError: if vocabulary_list is empty, or contains duplicate keys.
- ValueError: if dtype is not integer or string.

See Also

Other feature column constructors: [column_bucketized\(\)](#), [column_categorical_weighted\(\)](#), [column_categorical_with_hash_bucket\(\)](#), [column_categorical_with_identity\(\)](#), [column_categorical_with_vocabulary\(\)](#), [column_crossed\(\)](#), [column_embedding\(\)](#), [column_numeric\(\)](#), [input_layer\(\)](#)

column_crossed	<i>Construct a Crossed Column</i>
----------------	-----------------------------------

Description

Returns a column for performing crosses of categorical features. Crossed features will be hashed according to hash_bucket_size.

Usage

column_crossed(keys, hash_bucket_size, hash_key = NULL)

Arguments

keys

An iterable identifying the features to be crossed. Each element can be either:

- string: Will use the corresponding feature which must be of string type.
- categorical column: Will use the transformed tensor produced by this column. Does not support hashed categorical columns.

hash_bucket_size

The number of buckets (> 1).

hash_key

Optional: specify the hash_key that will be used by the FingerprintCat64 function to combine the crosses fingerprints on SparseCrossOp.

Value

A crossed column.

Raises

- `ValueError`: If `len(keys) < 2`.
- `ValueError`: If any of the keys is neither a string nor categorical column.
- `ValueError`: If any of the keys is `_HashedCategoricalColumn`.
- `ValueError`: If `hash_bucket_size < 1`.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_list()`, `column_embedding()`, `column_numeric()`, `input_layer()`

column_embedding

Construct a Dense Column

Description

Use this when your inputs are sparse, but you want to convert them to a dense representation (e.g., to feed to a DNN). Inputs must be a categorical column created by any of the `column_categorical_*`() functions.

Usage

```
column_embedding(
    categorical_column,
    dimension,
    combiner = "mean",
    initializer = NULL,
    ckpt_to_load_from = NULL,
    tensor_name_in_ckpt = NULL,
    max_norm = NULL,
    trainable = TRUE
)
```

Arguments

`categorical_column`

A categorical column created by a `column_categorical_*`() function. This column produces the sparse IDs that are inputs to the embedding lookup.

`dimension`

A positive integer, specifying dimension of the embedding.

combiner	A string specifying how to reduce if there are multiple entries in a single row. Currently "mean", "sqrtn" and "sum" are supported, with "mean" the default. "sqrtn" often achieves good accuracy, in particular with bag-of-words columns. Each of this can be thought as example level normalizations on the column.
initializer	A variable initializer function to be used in embedding variable initialization. If not specified, defaults to <code>tf\$truncated_normal_initializer</code> with mean 0.0 and standard deviation $1 / \sqrt{\text{dimension}}$.
ckpt_to_load_from	String representing checkpoint name/pattern from which to restore column weights. Required if <code>tensor_name_in_ckpt</code> is not NULL.
tensor_name_in_ckpt	Name of the Tensor in <code>ckpt_to_load_from</code> from which to restore the column weights. Required if <code>ckpt_to_load_from</code> is not NULL.
max_norm	If not NULL, embedding values are l2-normalized to this value.
trainable	Whether or not the embedding is trainable. Default is TRUE.

Value

A dense column that converts from sparse input.

Raises

- `ValueError`: if dimension not > 0 .
- `ValueError`: if exactly one of `ckpt_to_load_from` and `tensor_name_in_ckpt` is specified.
- `ValueError`: if `initializer` is specified and is not callable.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_numeric()`, `input_layer()`

column_indicator	<i>Represents Multi-Hot Representation of Given Categorical Column</i>
------------------	--

Description

Used to wrap any `column_categorical()*` (e.g., to feed to DNN). Use `column_embedding()` if the inputs are sparse.

Usage

```
column_indicator(categorical_column)
```

Arguments

categorical_column

A categorical column which is created by the column_categorical_with_*() or column_crossed() functions.

Value

An indicator column.

column_numeric	<i>Construct a Real-Valued Column</i>
----------------	---------------------------------------

Description

Construct a Real-Valued Column

Usage

```
column_numeric(
  ...,
  shape = c(1L),
  default_value = NULL,
  dtype = tf$float32,
  normalizer_fn = NULL
)
```

Arguments

...	Expression(s) identifying input feature(s). Used as the column name and the dictionary key for feature parsing configs, feature tensors, and feature columns.
shape	An integer vector that specifies the shape of the tensor. An integer can be given which means a single dimension tensor with given width. The tensor representing the column will have the shape of batch_size + shape.
default_value	A single value compatible with dtype or an iterable of values compatible with dtype which the column takes on during parsing if data is missing. A default value of NULL will cause tf\$parse_example to fail if an example does not contain this column. If a single value is provided, the same value will be applied as the default value for every item. If an iterable of values is provided, the shape of the default_value should be equal to the given shape.
dtype	The types for values contained in the column. The default value is tf\$float32. Must be a non-quantized, real integer or floating point type.
normalizer_fn	If not NULL, a function that can be used to normalize the value of the tensor after default_value is applied for parsing. Normalizer function takes the input Tensor as its argument, and returns the output tensor. (e.g. function(x) {(x - 3.0) / 4.2}). Please note that even though the most common use case of this function is normalization, it can be used for any kind of Tensorflow transformations.

Value

A numeric column.

Raises

- `TypeError`: if any dimension in `shape` is not an `int`
- `ValueError`: if any dimension in `shape` is not a positive integer
- `TypeError`: if `default_value` is an iterable but not compatible with `shape`
- `TypeError`: if `default_value` is not compatible with `dtype`
- `ValueError`: if `dtype` is not convertible to `tf$float32`

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_embedding()`, `input_layer()`

`dnn_estimators`*Deep Neural Networks*

Description

Create a deep neural network (DNN) estimator.

Usage

```
dnn_regressor(  
    hidden_units,  
    feature_columns,  
    model_dir = NULL,  
    label_dimension = 1L,  
    weight_column = NULL,  
    optimizer = "Adagrad",  
    activation_fn = "relu",  
    dropout = NULL,  
    input_layer_partitioner = NULL,  
    config = NULL  
)
```

```
dnn_classifier(  
    hidden_units,  
    feature_columns,  
    model_dir = NULL,  
    n_classes = 2L,  
    weight_column = NULL,  
    label_vocabulary = NULL,
```

```

optimizer = "Adagrad",
activation_fn = "relu",
dropout = NULL,
input_layer_partitioner = NULL,
config = NULL
)

```

Arguments

<code>hidden_units</code>	An integer vector, indicating the number of hidden units in each layer. All layers are fully connected. For example, <code>c(64, 32)</code> means the first layer has 64 nodes, and the second layer has 32 nodes.
<code>feature_columns</code>	An R list containing all of the feature columns used by the model (typically, generated by <code>feature_columns()</code>).
<code>model_dir</code>	Directory to save the model parameters, graph, and so on. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model.
<code>label_dimension</code>	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
<code>weight_column</code>	A string, or a numeric column created by <code>column_numeric()</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the <code>features</code> argument. If it is a numeric column, then the raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.
<code>optimizer</code>	Either the name of the optimizer to be used when training the model, or a TensorFlow optimizer instance. Defaults to the Adagrad optimizer.
<code>activation_fn</code>	The activation function to apply to each layer. This can either be an actual activation function (e.g. <code>tf\$nn\$relu</code>), or the name of an activation function (e.g. <code>"relu"</code>). Defaults to the <code>"relu"</code> activation function. See https://www.tensorflow.org/versions/r1.15/api_docs/python/tf/nn for documentation related to the set of activation functions available in TensorFlow.
<code>dropout</code>	When not NULL, the probability we will drop out a given coordinate.
<code>input_layer_partitioner</code>	An optional partitioner for the input layer. Defaults to <code>min_max_variable_partitioner</code> with <code>min_slice_size</code> <code>64 < 20</code> .
<code>config</code>	A run configuration created by <code>run_config()</code> , used to configure the runtime settings.
<code>n_classes</code>	The number of label classes.
<code>label_vocabulary</code>	A list of strings represents possible label values. If given, labels must be string type and have any value in <code>label_vocabulary</code> . If it is not given, that means labels are already encoded as integer or float within <code>[0, 1]</code> for <code>n_classes == 2</code> and encoded as integer values in <code>{0, 1, ..., n_classes - 1}</code> for <code>n_classes > 2</code> . Also there will be errors if vocabulary is not provided and labels are string.

`dnn_linear_combined_estimators`

Linear Combined Deep Neural Networks

Description

Also known as wide-n-deep estimators, these are estimators for TensorFlow Linear and DNN joined models for regression.

Usage

```
dnn_linear_combined_regressor(  
  model_dir = NULL,  
  linear_feature_columns = NULL,  
  linear_optimizer = "Ftrl",  
  dnn_feature_columns = NULL,  
  dnn_optimizer = "Adagrad",  
  dnn_hidden_units = NULL,  
  dnn_activation_fn = "relu",  
  dnn_dropout = NULL,  
  label_dimension = 1L,  
  weight_column = NULL,  
  input_layer_partitioner = NULL,  
  config = NULL  
)
```

```
dnn_linear_combined_classifier(  
  model_dir = NULL,  
  linear_feature_columns = NULL,  
  linear_optimizer = "Ftrl",  
  dnn_feature_columns = NULL,  
  dnn_optimizer = "Adagrad",  
  dnn_hidden_units = NULL,  
  dnn_activation_fn = "relu",  
  dnn_dropout = NULL,  
  n_classes = 2L,  
  weight_column = NULL,  
  label_vocabulary = NULL,  
  input_layer_partitioner = NULL,  
  config = NULL  
)
```

Arguments

<code>model_dir</code>	Directory to save the model parameters, graph, and so on. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model.
<code>linear_feature_columns</code>	The feature columns used by linear (wide) part of the model.
<code>linear_optimizer</code>	Either the name of the optimizer to be used when training the model, or a TensorFlow optimizer instance. Defaults to the FTRL optimizer.
<code>dnn_feature_columns</code>	The feature columns used by the neural network (deep) part in the model.
<code>dnn_optimizer</code>	Either the name of the optimizer to be used when training the model, or a TensorFlow optimizer instance. Defaults to the Adagrad optimizer.
<code>dnn_hidden_units</code>	An integer vector, indicating the number of hidden units in each layer. All layers are fully connected. For example, <code>c(64, 32)</code> means the first layer has 64 nodes, and the second layer has 32 nodes.
<code>dnn_activation_fn</code>	The activation function to apply to each layer. This can either be an actual activation function (e.g. <code>tf.nn.relu</code>), or the name of an activation function (e.g. <code>"relu"</code>). Defaults to the <code>"relu"</code> activation function. See https://www.tensorflow.org/versions/r1.15/api_docs/python/tf/nn for documentation related to the set of activation functions available in TensorFlow.
<code>dnn_dropout</code>	When not NULL, the probability we will drop out a given coordinate.
<code>label_dimension</code>	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
<code>weight_column</code>	A string, or a numeric column created by <code>column_numeric()</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the features argument. If it is a numeric column, then the raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.
<code>input_layer_partitioner</code>	An optional partitioner for the input layer. Defaults to <code>min_max_variable_partitioner</code> with <code>min_slice_size 64 « 20</code> .
<code>config</code>	A run configuration created by <code>run_config()</code> , used to configure the runtime settings.
<code>n_classes</code>	The number of label classes.
<code>label_vocabulary</code>	A list of strings represents possible label values. If given, labels must be string type and have any value in <code>label_vocabulary</code> . If it is not given, that means labels are already encoded as integer or float within <code>[0, 1]</code> for <code>n_classes == 2</code> and encoded as integer values in <code>{0, 1, ..., n_classes - 1}</code> for <code>n_classes > 2</code> . Also there will be errors if vocabulary is not provided and labels are string.

Other canned estimators: [boosted_trees_estimators](#), [dnn_estimators](#), [linear_estimators](#)

estimator	<i>Construct a Custom Estimator</i>
-----------	-------------------------------------

Description

Construct a custom estimator, to be used to train and evaluate TensorFlow models.

Usage

```
estimator(
    model_fn,
    model_dir = NULL,
    config = NULL,
    params = NULL,
    class = NULL
)
```

Arguments

model_fn	The model function. See Model Function for details on the structure of a model function.
model_dir	Directory to save model parameters, graph and etc. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model. If NULL, the model_dir in config will be used if set. If both are set, they must be same. If both are NULL, a temporary directory will be used.
config	Configuration object.
params	List of hyper parameters that will be passed into model_fn. Keys are names of parameters, values are basic python types.
class	An optional set of R classes to add to the generated object.

Details

The Estimator object wraps a model which is specified by a model_fn, which, given inputs and a number of other parameters, returns the operations necessary to perform training, evaluation, and prediction.

All outputs (checkpoints, event files, etc.) are written to model_dir, or a subdirectory thereof. If model_dir is not set, a temporary directory is used.

The config argument can be used to passed run configuration object containing information about the execution environment. It is passed on to the model_fn, if the model_fn has a parameter named "config" (and input functions in the same manner). If the config parameter is not passed, it is instantiated by estimator(). Not passing config means that defaults useful for local execution are used. estimator() makes config available to the model (for instance, to allow specialization based

on the number of workers available), and also uses some of its fields to control internals, especially regarding checkpointing.

The `params` argument contains hyperparameters. It is passed to the `model_fn`, if the `model_fn` has a parameter named "params", and to the input functions in the same manner. `estimator()` only passes `params` along, it does not inspect it. The structure of `params` is therefore entirely up to the developer.

None of `estimator`'s methods can be overridden in subclasses (its constructor enforces this). Subclasses should use `model_fn` to configure the base class, and may add methods implementing specialized functionality.

Model Functions

The `model_fn` should be an R function of the form:

```
function(features, labels, mode, params) {
  # 1. Configure the model via TensorFlow operations.
  # 2. Define the loss function for training and evaluation.
  # 3. Define the training optimizer.
  # 4. Define how predictions should be produced.
  # 5. Return the result as an `estimator_spec()` object.
  estimator_spec(mode, predictions, loss, train_op, eval_metric_ops)
}
```

The model function's inputs are defined as follows:

<code>features</code>	The feature tensor(s).
<code>labels</code>	The label tensor(s).
<code>mode</code>	The current training mode ("train", "eval", "infer"). These can be accessed through the <code>mode_keys()</code> object.
<code>params</code>	An optional list of hyperparameters, as received through the <code>estimator()</code> constructor.

See `estimator_spec()` for more details as to how the estimator specification should be constructed, and https://www.tensorflow.org/versions/r1.15/api_docs/python/tf/estimator/Estimator for more information as to how the model function should be constructed.

See Also

Other custom estimator methods: `estimator_spec()`, `evaluate.tf_estimator()`, `export_savedmodel.tf_estimator()`, `predict.tf_estimator()`, `train.tf_estimator()`

Description

Base Documentation for Canned Estimators

Arguments

object	A TensorFlow estimator.
feature_columns	An R list containing all of the feature columns used by the model (typically, generated by <code>feature_columns()</code>).
model_dir	Directory to save the model parameters, graph, and so on. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model.
label_dimension	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
label_vocabulary	A list of strings represents possible label values. If given, labels must be string type and have any value in <code>label_vocabulary</code> . If it is not given, that means labels are already encoded as integer or float within <code>[0, 1]</code> for <code>n_classes == 2</code> and encoded as integer values in <code>{0, 1, ..., n_classes - 1}</code> for <code>n_classes > 2</code> . Also there will be errors if vocabulary is not provided and labels are string.
weight_column	A string, or a numeric column created by <code>column_numeric()</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the <code>features</code> argument. If it is a numeric column, then the raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.
n_classes	The number of label classes.
config	A run configuration created by <code>run_config()</code> , used to configure the runtime settings.
input_layer_partitioner	An optional partitioner for the input layer. Defaults to <code>min_max_variable_partitioner</code> with <code>min_slice_size 64 < 20</code> .
partitioner	An optional partitioner for the input layer.

estimator_spec	<i>Define an Estimator Specification</i>
----------------	--

Description

Define the estimator specification, used as part of the `model_fn` defined with custom estimators created by `estimator()`. See `estimator()` for more details.

Usage

```
estimator_spec(
  mode,
  predictions = NULL,
  loss = NULL,
  train_op = NULL,
  eval_metric_ops = NULL,
  training_hooks = NULL,
  evaluation_hooks = NULL,
  prediction_hooks = NULL,
  training_chief_hooks = NULL,
  ...
)
```

Arguments

mode	A key that specifies whether we are performing training ("train"), evaluation ("eval"), or prediction ("infer"). These values can also be accessed through the <code>mode_keys()</code> object.
predictions	The prediction tensor(s).
loss	The training loss tensor. Must be either scalar, or with shape <code>c(1)</code> .
train_op	The training operation – typically, a call to <code>optimizer\$minimize(...)</code> , depending on the type of optimizer used during training.
eval_metric_ops	A list of metrics to be computed as part of evaluation. This should be a named list, mapping metric names (e.g. "rmse") to the operation that computes the associated metric (e.g. <code>tf\$metrics\$root_mean_squared_error(...)</code>). These metric operations should be evaluated without any impact on state (typically is a pure computation results based on variables). For example, it should not trigger the update ops or requires any input fetching.
training_hooks	(Available since TensorFlow v1.4) A list of session run hooks to run on all workers during training.
evaluation_hooks	(Available since TensorFlow v1.4) A list of session run hooks to run during evaluation.

prediction_hooks
 (Available since TensorFlow v1.7) A list of session run hooks to run during prediction.

training_chief_hooks
 (Available since TensorFlow v1.4) A list of session run hooks to run on chief worker during training.

...
 Other optional (named) arguments, to be passed to the EstimatorSpec constructor.

evaluate.tf_estimator *Evaluate an Estimator*

Description

Evaluate an estimator on input data provided by an `input_fn()`.

Usage

```
## S3 method for class 'tf_estimator'
evaluate(
  object,
  input_fn,
  steps = NULL,
  checkpoint_path = NULL,
  name = NULL,
  hooks = NULL,
  simplify = TRUE,
  ...
)
```

Arguments

`object` A TensorFlow estimator.

`input_fn` An input function, typically generated by the [input_fn\(\)](#) helper function.

`steps` The number of steps for which the model should be evaluated on this particular `evaluate()` invocation. If NULL (the default), this function will either evaluate forever, or until the supplied `input_fn()` has provided all available data.

`checkpoint_path` The path to a specific model checkpoint to be used for prediction. If NULL (the default), the latest checkpoint in `model_dir` is used.

name	Name of the evaluation if user needs to run multiple evaluations on different data sets, such as on training data vs test data. Metrics for different evaluations are saved in separate folders, and appear separately in tensorboard.
hooks	A list of R functions, to be used as callbacks inside the training loop. By default, <code>hook_history_saver(every_n_step = 10)</code> and <code>hook_progress_bar()</code> will be attached if not provided to save the metrics history and create the progress bar.
simplify	Whether to simplify evaluation results into a tibble, as opposed to a list. Defaults to TRUE.
...	Optional arguments passed on to the estimator's <code>evaluate()</code> method.

Details

For each step, this method will call `input_fn()` to produce a single batch of data. Evaluation continues until:

- steps batches are processed, or
- The `input_fn()` is exhausted of data.

Value

An R list of evaluation metrics.

See Also

Other custom estimator methods: [estimator\(\)](#), [estimator_spec\(\)](#), [export_savedmodel.tf_estimator\(\)](#), [predict.tf_estimator\(\)](#), [train.tf_estimator\(\)](#)

eval_spec

Configuration for the eval component of train_and_evaluate

Description

EvalSpec combines details of evaluation of the trained model as well as its export. Evaluation consists of computing metrics to judge the performance of the trained model. Export writes out the trained model on to external storage.

Usage

```
eval_spec(
  input_fn,
  steps = 100,
  name = NULL,
  hooks = NULL,
  exporters = NULL,
  start_delay_secs = 120,
  throttle_secs = 600
)
```

Arguments

input_fn	Evaluation input function returning a tuple of: • features - Tensor or dictionary of string feature name to Tensor. • labels - Tensor or dictionary of Tensor with labels.
steps	Positive number of steps for which to evaluate model. If NULL, evaluates until input_fn raises an end-of-input exception.
name	Name of the evaluation if user needs to run multiple evaluations on different data sets. Metrics for different evaluations are saved in separate folders, and appear separately in tensorboard.
hooks	List of session run hooks to run during evaluation.
exporters	List of Exporters, or a single one, or NULL. exporters will be invoked after each evaluation.
start_delay_secs	Start evaluating after waiting for this many seconds.
throttle_secs	Do not re-evaluate unless the last evaluation was started at least this many seconds ago. Of course, evaluation does not occur if no new checkpoints are available, hence, this is the minimum.

See Also

Other training methods: [train_and_evaluate.tf_estimator\(\)](#), [train_spec\(\)](#)

experiment	<i>Construct an Experiment</i>
------------	--------------------------------

Description

Construct an experiment object.

Usage

```
experiment(object, ...)
```

Arguments

object	An R object.
...	Optional arguments passed on to implementing methods.

export_savedmodel.tf_estimator
Save an Estimator

Description

Save an estimator (alongside its weights) to the directory export_dir_base.

Usage

```
## S3 method for class 'tf_estimator'
export_savedmodel(
  object,
  export_dir_base,
  serving_input_receiver_fn = NULL,
  assets_extra = NULL,
  as_text = FALSE,
  checkpoint_path = NULL,
  overwrite = TRUE,
  versioned = !overwrite,
  ...
)
```

Arguments

object	A TensorFlow estimator.
export_dir_base	A string containing a directory in which to export the SavedModel.
serving_input_receiver_fn	A function that takes no argument and returns a ServingInputReceiver. Required for custom models.
assets_extra	A dict specifying how to populate the assets.extra directory within the exported SavedModel, or NULL if no extra assets are needed.
as_text	whether to write the SavedModel proto in text format.
checkpoint_path	The checkpoint path to export. If NULL (the default), the most recent checkpoint found within the model directory is chosen.
overwrite	Should the export_dir directory be overwritten?
versioned	Should the model be exported under a versioned subdirectory?
...	Optional arguments passed on to the estimator's export_savedmodel() method.

Details

This method builds a new graph by first calling the `serving_input_receiver_fn` to obtain feature Tensors, and then calling this Estimator's `model_fn` to generate the model graph based on those features. It restores the given checkpoint (or, lacking that, the most recent checkpoint) into this graph in a fresh session. Finally it creates a timestamped export directory below the given `export_dir_base`, and writes a SavedModel into it containing a single MetaGraphDef saved from this session. The exported MetaGraphDef will provide one SignatureDef for each element of the `export_outputs` dict returned from the `model_fn`, named using the same keys. One of these keys is always `signature_constants.DEFAULT_SERVING_SIGNATURE_DEF_KEY`, indicating which signature will be served when a serving request does not specify one. For each signature, the outputs are provided by the corresponding ExportOutputs, and the inputs are always the input receivers provided by the `serving_input_receiver_fn`. Extra assets may be written into the SavedModel via the `extra_assets` argument. This should be a dict, where each key gives a destination path (including the filename) relative to the `assets.extra` directory. The corresponding value gives the full path of the source file to be copied. For example, the simple case of copying a single file without renaming it is specified as `{'my_asset_file.txt': '/path/to/my_asset_file.txt'}`.

Value

The path to the exported directory, as a string.

Raises

ValueError: if no `serving_input_receiver_fn` is provided, no `export_outputs` are provided, or no checkpoint can be found.

feature_columns	<i>Feature Columns</i>
-----------------	------------------------

Description

Constructors for feature columns. A feature column defines the expected 'shape' of an input Tensor.

Usage

```
feature_columns(..., names = NULL)
```

Arguments

- ... One or more feature column definitions. The [tidyselect](#) package is used to power generation of feature columns.
- names Available feature names (for selection / pattern matching) as a character vector (or R object that implements `names()` or `colnames()`).

graph_keys

*Standard Names to Use for Graph Collections***Description**

The standard library uses various well-known names to collect and retrieve values associated with a graph.

Usage

```
graph_keys()
```

Details

For example, the `tf$Optimizer` subclasses default to optimizing the variables collected under `graph_keys()$TRAINABLE_VARIABLES` if `NULL` is specified, but it is also possible to pass an explicit list of variables.

The following standard keys are defined:

- **GLOBAL_VARIABLES**: the default collection of `Variable` objects, shared across distributed environment (model variables are subset of these). See `tf$global_variables` for more details. Commonly, all `TRAINABLE_VARIABLES` variables will be in `MODEL_VARIABLES`, and all `MODEL_VARIABLES` variables will be in `GLOBAL_VARIABLES`.
- **LOCAL_VARIABLES**: the subset of `Variable` objects that are local to each machine. Usually used for temporarily variables, like counters. Note: use `tf$contrib$framework$local_variable` to add to this collection.
- **MODEL_VARIABLES**: the subset of `Variable` objects that are used in the model for inference (feed forward). Note: use `tf$contrib$framework$model_variable` to add to this collection.
- **TRAINABLE_VARIABLES**: the subset of `Variable` objects that will be trained by an optimizer. See `tf$trainable_variables` for more details.
- **SUMMARIES**: the summary `Tensor` objects that have been created in the graph. See `tf$summary$merge_all` for more details.
- **QUEUE_RUNNERS**: the `QueueRunner` objects that are used to produce input for a computation. See `tf$train$start_queue_runners` for more details.
- **MOVING_AVERAGE_VARIABLES**: the subset of `Variable` objects that will also keep moving averages. See `tf$moving_average_variables` for more details.
- **REGULARIZATION_LOSSES**: regularization losses collected during graph construction. The following standard keys are defined, but their collections are **not** automatically populated as many of the others are:
 - `WEIGHTS`
 - `BIASES`
 - `ACTIVATIONS`

Examples

```
## Not run:
graph_keys()
graph_keys()$LOSSES

## End(Not run)
```

hook_checkpoint_saver *Saves Checkpoints Every N Steps or Seconds*

Description

Saves Checkpoints Every N Steps or Seconds

Usage

```
hook_checkpoint_saver(
  checkpoint_dir,
  save_secs = NULL,
  save_steps = NULL,
  saver = NULL,
  checkpoint_basename = "model.ckpt",
  scaffold = NULL,
  listeners = NULL
)
```

Arguments

checkpoint_dir	The base directory for the checkpoint files.
save_secs	An integer, indicating saving checkpoints every N secs.
save_steps	An integer, indicating saving checkpoints every N steps.
saver	A saver object, used for saving.
checkpoint_basename	The base name for the checkpoint files.
scaffold	A scaffold, used to get saver object.
listeners	List of checkpoint saver listener subclass instances, used for callbacks that run immediately after the corresponding hook_checkpoint_saver callbacks, only in steps where the hook_checkpoint_saver was triggered.

hook_global_step_waiter

Delay Execution until Global Step Reaches to wait_until_step.

Description

This hook delays execution until global step reaches to wait_until_step. It is used to gradually start workers in distributed settings. One example usage would be setting wait_until_step=int(K*log(task_id+1)) assuming that task_id=0 is the chief.

Usage

```
hook_global_step_waiter(wait_until_step)
```

Arguments

wait_until_step

An integer indicating that until which global step should we wait.

See Also

Other session_run_hook wrappers: [hook_checkpoint_saver\(\)](#), [hook_history_saver\(\)](#), [hook_logging_tensor\(\)](#), [hook_nan_tensor\(\)](#), [hook_progress_bar\(\)](#), [hook_step_counter\(\)](#), [hook_stop_at_step\(\)](#), [hook_summary_saver\(\)](#), [session_run_hook\(\)](#)

hook_history_saver

A Custom Run Hook for Saving Metrics History

Description

This hook allows users to save the metrics history produced during training or evaluation in a specified frequency.

Usage

```
hook_history_saver(every_n_step = 10)
```

Arguments

every_n_step Save the metrics every N steps

See Also

Other session_run_hook wrappers: [hook_checkpoint_saver\(\)](#), [hook_global_step_waiter\(\)](#), [hook_logging_tensor\(\)](#), [hook_nan_tensor\(\)](#), [hook_progress_bar\(\)](#), [hook_step_counter\(\)](#), [hook_stop_at_step\(\)](#), [hook_summary_saver\(\)](#), [session_run_hook\(\)](#)

hook_logging_tensor *Prints Given Tensors Every N Local Steps, Every N Seconds, or at End*

Description

The tensors will be printed to the log, with INFO severity.

Usage

```
hook_logging_tensor(
    tensors,
    every_n_iter = NULL,
    every_n_secs = NULL,
    formatter = NULL,
    at_end = FALSE
)
```

Arguments

tensors	A list that maps string-valued tags to tensors/tensor names.
every_n_iter	An integer value, indicating the values of tensors will be printed once every N local steps taken on the current worker.
every_n_secs	An integer or float value, indicating the values of tensors will be printed once every N seconds. Exactly one of every_n_iter and every_n_secs should be provided.
formatter	A function that takes list(tag = tensor) and returns a string. If NULL uses default printing all tensors.
at_end	A boolean value specifying whether to print the values of tensors at the end of the run.

Details

Note that if at_end is TRUE, tensors should not include any tensor whose evaluation produces a side effect such as consuming additional inputs.

See Also

hook_nan_tensor	<i>NaN Loss Monitor</i>
-----------------	-------------------------

Description

Monitors loss and stops training if loss is NaN. Can either fail with exception or just stop training.

Usage

```
hook_nan_tensor(loss_tensor, fail_on_nan_loss = TRUE)
```

Arguments

loss_tensor The loss tensor.

fail_on_nan_loss
 A boolean indicating whether to raise exception when loss is NaN.

hook_step_counter	<i>Steps per Second Monitor</i>
-------------------	---------------------------------

Description

Steps per Second Monitor

Usage

```
hook_step_counter(  
    every_n_steps = 100,  
    every_n_secs = NULL,  
    output_dir = NULL,  
    summary_writer = NULL  
)
```

Arguments

every_n_steps	Run this counter every N steps
every_n_secs	Run this counter every N seconds
output_dir	The output directory
summary_writer	The summary writer

See Also

hook_stop_at_step	<i>Monitor to Request Stop at a Specified Step</i>
-------------------	--

Description

Monitor to Request Stop at a Specified Step

Usage

```
hook_stop_at_step(num_steps = NULL, last_step = NULL)
```

Arguments

num_steps	Number of steps to execute.
last_step	Step after which to stop.

See Also

Other session_run_hook wrappers: [hook_checkpoint_saver\(\)](#), [hook_global_step_waiter\(\)](#), [hook_history_saver\(\)](#), [hook_logging_tensor\(\)](#), [hook_nan_tensor\(\)](#), [hook_progress_bar\(\)](#), [hook_step_counter\(\)](#), [hook_summary_saver\(\)](#), [session_run_hook\(\)](#)

hook_summary_saver	<i>Saves Summaries Every N Steps</i>
--------------------	--------------------------------------

Description

Saves Summaries Every N Steps

Usage

```
hook_summary_saver(
    save_steps = NULL,
    save_secs = NULL,
    output_dir = NULL,
    summary_writer = NULL,
    scaffold = NULL,
    summary_op = NULL
)
```

Arguments

save_steps	An integer indicating saving summaries every N steps. Exactly one of save_secs and save_steps should be set.
save_secs	An integer indicating saving summaries every N seconds.
output_dir	The directory to save the summaries to. Only used if no summary_writer is supplied.
summary_writer	The summary writer. If NULL and an output_dir was passed, one will be created accordingly.
scaffold	A scaffold to get summary_op if it's not provided.
summary_op	A tensor of type tf\$string containing the serialized summary protocol buffer or a list of tensors. They are most likely an output by TensorFlow summary methods like tf\$summary\$scalar or tf\$summary\$merge_all. It can be passed in as one tensor; if more than one, they must be passed in as a list.

input_fn	<i>Construct an Input Function</i>
----------	------------------------------------

Description

This function constructs input function from various types of input used to feed different Tensor-Flow estimators.

Usage

```
input_fn(object, ...)

## Default S3 method:
input_fn(object, ...)

## S3 method for class 'formula'
input_fn(object, data, ...)

## S3 method for class 'data.frame'
input_fn(
  object,
  features,
  response = NULL,
  batch_size = 128,
  shuffle = "auto",
  num_epochs = 1,
  queue_capacity = 1000,
  num_threads = 1,
  ...
)

## S3 method for class 'list'
input_fn(
  object,
  features,
  response = NULL,
  batch_size = 128,
  shuffle = "auto",
  num_epochs = 1,
  queue_capacity = 1000,
  num_threads = 1,
  ...
)

## S3 method for class 'matrix'
input_fn(object, ...)
```

Arguments

object, data	An 'input source' – either a data set (e.g. an <code>R data.frame</code>), or another kind of object that can provide the data required for training.
...	Optional arguments passed on to implementing submethods.
features	The names of feature variables to be used.
response	The name of the response variable.
batch_size	The batch size.
shuffle	Whether to shuffle the queue. When "auto" (the default), shuffling will be performed except when this input function is called by a <code>predict()</code> method.
num_epochs	The number of epochs to iterate over data.
queue_capacity	The size of queue to accumulate.
num_threads	The number of threads used for reading and enqueueing. In order to have predictable and repeatable order of reading and enqueueing, such as in prediction and evaluation mode, <code>num_threads</code> should be 1.

Details

For list objects, this method is particularly useful when constructing dynamic length of inputs for models like recurrent neural networks. Note that some arguments are not available yet for `input_fn` applied to list objects. See S3 method signatures below for more details.

Examples

```
## Not run:
# Construct the input function through formula interface
input_fn1 <- input_fn(mpg ~ drat + cyl, mtcars)

## End(Not run)

## Not run:
# Construct the input function from a data.frame object
input_fn1 <- input_fn(mtcars, response = mpg, features = c(drat, cyl))

## End(Not run)

## Not run:
# Construct the input function from a list object
input_fn1 <- input_fn(
  object = list(
    feature1 = list(
      list(list(1), list(2), list(3)),
      list(list(4), list(5), list(6))),
    feature2 = list(
      list(list(7), list(8), list(9)),
```

```

        list(list(10), list(11), list(12))),
        response = list(
            list(1, 2, 3), list(4, 5, 6))),
        features = c("feature1", "feature2"),
        response = "response",
        batch_size = 10L)

## End(Not run)

```

input_layer

*Construct an Input Layer***Description**

Returns a dense tensor as input layer based on given `feature_columns`. At the first layer of the model, this column oriented data should be converted to a single tensor.

Usage

```

input_layer(
  features,
  feature_columns,
  weight_collections = NULL,
  trainable = TRUE
)

```

Arguments

<code>features</code>	A mapping from key to tensors. Feature columns look up via these keys. For example <code>column_numeric('price')</code> will look at 'price' key in this dict. Values can be a sparse tensor or tensor depends on corresponding feature column.
<code>feature_columns</code>	An iterable containing the <code>FeatureColumns</code> to use as inputs to your model. All items should be instances of classes derived from a dense column such as <code>column_numeric()</code> , <code>column_embedding()</code> , <code>column_bucketized()</code> , <code>column_indicator()</code> . If you have categorical features, you can wrap them with an <code>column_embedding()</code> or <code>column_indicator()</code> .
<code>weight_collections</code>	A list of collection names to which the <code>Variable</code> will be added. Note that, variables will also be added to collections <code>graph_keys()\$GLOBAL_VARIABLES</code> and <code>graph_keys()\$MODEL_VARIABLES</code> .
<code>trainable</code>	If <code>TRUE</code> also add the variable to the graph collection <code>graph_keys()\$TRAINABLE_VARIABLES</code> (see <code>tf\$Variable</code>).

Value

A tensor which represents input layer of a model. Its shape is `(batch_size, first_layer_dimension)` and its dtype is `float32`. `first_layer_dimension` is determined based on given `feature_columns`.

Raises

- `ValueError`: if an item in `feature_columns` is not a dense column.

See Also

Other feature column constructors: `column_bucketized()`, `column_categorical_weighted()`, `column_categorical_with_hash_bucket()`, `column_categorical_with_identity()`, `column_categorical_with_vocabulary_list()`, `column_crossed()`, `column_embedding()`, `column_numeric()`

keras_model_to_estimator

Keras Estimators

Description

Create an Estimator from a compiled Keras model

Usage

```
keras_model_to_estimator(
    keras_model = NULL,
    keras_model_path = NULL,
    custom_objects = NULL,
    model_dir = NULL,
    config = NULL
)
```

Arguments

<code>keras_model</code>	A keras model.
<code>keras_model_path</code>	Directory to a keras model on disk.
<code>custom_objects</code>	Dictionary for custom objects.
<code>model_dir</code>	Directory to save Estimator model parameters, graph and etc.
<code>config</code>	Configuration object.

latest_checkpoint	<i>Get the Latest Checkpoint in a Checkpoint Directory</i>
-------------------	--

Description

Get the Latest Checkpoint in a Checkpoint Directory

Usage

```
latest_checkpoint(checkpoint_dir, ...)
```

Arguments

checkpoint_dir The path to the checkpoint directory.

... Optional arguments passed on to latest_checkpoint().

See Also

Other utility functions: [graph_keys\(\)](#)

linear_estimators	<i>Construct a Linear Estimator</i>
-------------------	-------------------------------------

Description

Construct a linear model, which can be used to predict a continuous outcome (in the case of `linear_regressor()`) or a categorical outcome (in the case of `linear_classifier()`).

Usage

```
linear_regressor(  
  feature_columns,  
  model_dir = NULL,  
  label_dimension = 1L,  
  weight_column = NULL,  
  optimizer = "Ftrl",  
  config = NULL,  
  partitioner = NULL  
)
```

```
linear_classifier(  
  feature_columns,  
  model_dir = NULL,  
  n_classes = 2L,  
  weight_column = NULL,
```

```

    label_vocabulary = NULL,
    optimizer = "Ftrl",
    config = NULL,
    partitioner = NULL
)

```

Arguments

<code>feature_columns</code>	An R list containing all of the feature columns used by the model (typically, generated by <code>feature_columns()</code>).
<code>model_dir</code>	Directory to save the model parameters, graph, and so on. This can also be used to load checkpoints from the directory into a estimator to continue training a previously saved model.
<code>label_dimension</code>	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
<code>weight_column</code>	A string, or a numeric column created by <code>column_numeric()</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the <code>features</code> argument. If it is a numeric column, then the raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.
<code>optimizer</code>	Either the name of the optimizer to be used when training the model, or a TensorFlow optimizer instance. Defaults to the FTRL optimizer.
<code>config</code>	A run configuration created by <code>run_config()</code> , used to configure the runtime settings.
<code>partitioner</code>	An optional partitioner for the input layer.
<code>n_classes</code>	The number of label classes.
<code>label_vocabulary</code>	A list of strings represents possible label values. If given, labels must be string type and have any value in <code>label_vocabulary</code> . If it is not given, that means labels are already encoded as integer or float within <code>[0, 1]</code> for <code>n_classes == 2</code> and encoded as integer values in <code>{0, 1, ..., n_classes - 1}</code> for <code>n_classes > 2</code> . Also there will be errors if vocabulary is not provided and labels are string.

Other canned estimators: `boosted_trees_estimators`, `dnn_estimators`, `dnn_linear_combined_estimators`

metric_keys	<i>Canonical Metric Keys</i>
-------------	------------------------------

Description

The canonical set of keys that can be used to access metrics from canned estimators.

Usage

```
metric_keys()
```

See Also

Other estimator keys: [mode_keys\(\)](#), [prediction_keys\(\)](#)

Examples

```
## Not run:
metrics <- metric_keys()

# Get the available keys
metrics

metrics$ACCURACY

## End(Not run)
```

model_dir	<i>Model directory</i>
-----------	------------------------

Description

Get the directory where a model’s artifacts are stored.

Usage

```
model_dir(object, ...)
```

Arguments

object	Model object
...	Unused

mode_keys	<i>Canonical Mode Keys</i>
-----------	----------------------------

Description

The names for different possible modes for an estimator. The following standard keys are defined:

Usage

```
mode_keys()
```

Details

TRAIN	Training mode.
EVAL	Evaluation mode.
PREDICT	Prediction / inference mode.

See Also

Other estimator keys: [metric_keys\(\)](#), [prediction_keys\(\)](#)

Examples

```
## Not run:
modes <- mode_keys()
modes$TRAIN

## End(Not run)
```

numpy_input_fn	<i>Construct Input Function Containing Python Dictionaries of Numpy Arrays</i>
----------------	--

Description

This returns a function outputting features and target based on the dict of numpy arrays. The dict features has the same keys as the x.

Usage

```
numpy_input_fn(
    x,
    y = NULL,
    batch_size = 128,
    num_epochs = 1,
    shuffle = NULL,
    queue_capacity = 1000,
    num_threads = 1
)
```

Arguments

x	dict of numpy array object.
y	numpy array object. NULL if absent.
batch_size	Integer, size of batches to return.
num_epochs	Integer, number of epochs to iterate over data. If NULL will run forever.
shuffle	Boolean, if TRUE shuffles the queue. Avoid shuffle at prediction time.
queue_capacity	Integer, size of queue to accumulate.
num_threads	Integer, number of threads used for reading and enqueueing. In order to have predicted and repeatable order of reading and enqueueing, such as in prediction and evaluation mode, num_threads should be 1. #'

Details

Note that this function is still experimental and should only be used if necessary, e.g. feed in data that's dictionary of numpy arrays.

Raises

ValueError: if the shape of y mismatches the shape of values in x (i.e., values in x have same shape).
 TypeError: x is not a dict or shuffle is not bool.

See Also

Other input functions: [input_fn\(\)](#)

plot.tf_estimator_history

Plot training history

Description

Plots metrics recorded during training.

Usage

```
## S3 method for class 'tf_estimator_history'
plot(
  x,
  y,
  metrics = NULL,
  method = c("auto", "ggplot2", "base"),
  smooth = getOption("tf.estimator.plot.history.smooth", TRUE),
  theme_bw = getOption("tf.estimator.plot.history.theme_bw", FALSE),
  ...
)
```

Arguments

x	Training history object returned from <code>train()</code> .
y	Unused.
metrics	One or more metrics to plot (e.g. <code>c('total_losses', 'mean_losses')</code>). Defaults to plotting all captured metrics.
method	Method to use for plotting. The default "auto" will use ggplot2 if available, and otherwise will use base graphics.
smooth	Whether a loess smooth should be added to the plot, only available for the <code>ggplot2</code> method. If the number of data points is smaller than ten, it is forced to false.
theme_bw	Use <code>ggplot2::theme_bw()</code> to plot the history in black and white.
...	Additional parameters to pass to the <code>plot()</code> method.

predict.tf_estimator *Generate Predictions with an Estimator*

Description

Generate predicted labels / values for input data provided by `input_fn()`.

Usage

```
## S3 method for class 'tf_estimator'
predict(
  object,
  input_fn,
  checkpoint_path = NULL,
  predict_keys = c("predictions", "classes", "class_ids", "logistic", "logits",
    "probabilities"),
  hooks = NULL,
  as_iterable = FALSE,
  simplify = TRUE,
```

```

    yield_single_examples = TRUE,
    ...
)

```

Arguments

<code>object</code>	A TensorFlow estimator.
<code>input_fn</code>	An input function, typically generated by the <code>input_fn()</code> helper function.
<code>checkpoint_path</code>	The path to a specific model checkpoint to be used for prediction. If NULL (the default), the latest checkpoint in <code>model_dir</code> is used.
<code>predict_keys</code>	The types of predictions that should be produced, as an R list. When this argument is not specified (the default), all possible predicted values will be returned.
<code>hooks</code>	A list of R functions, to be used as callbacks inside the training loop. By default, <code>hook_history_saver(every_n_step = 10)</code> and <code>hook_progress_bar()</code> will be attached if not provided to save the metrics history and create the progress bar.
<code>as_iterable</code>	Boolean; should a raw Python generator be returned? When FALSE (the default), the predicted values will be consumed from the generator and returned as an R object.
<code>simplify</code>	Whether to simplify prediction results into a tibble, as opposed to a list. Defaults to TRUE.
<code>yield_single_examples</code>	(Available since TensorFlow v1.7) If FALSE, yields the whole batch as returned by the <code>model_fn</code> instead of decomposing the batch into individual elements. This is useful if <code>model_fn</code> returns some tensors with first dimension not equal to the batch size.
<code>...</code>	Optional arguments passed on to the estimator's <code>predict()</code> method.

Yields

Evaluated values of predictions tensors.

Raises

`ValueError`: Could not find a trained model in `model_dir`. `ValueError`: if batch length of predictions are not same. `ValueError`: If there is a conflict between `predict_keys` and predictions. For example if `predict_keys` is not NULL but `EstimatorSpec.predictions` is not a dict.

See Also

Other custom estimator methods: `estimator()`, `estimator_spec()`, `evaluate.tf_estimator()`, `export_savedmodel.tf_estimator()`, `train.tf_estimator()`

prediction_keys	<i>Canonical Model Prediction Keys</i>
-----------------	--

Description

The canonical set of keys used for models and estimators that provide different types of predicted values through their `predict()` method.

Usage

```
prediction_keys()
```

See Also

Other estimator keys: [metric_keys\(\)](#), [mode_keys\(\)](#)

Examples

```
## Not run:
keys <- prediction_keys()

# Get the available keys
keys

# Key for retrieving probabilities from prediction values
keys$PROBABILITIES

## End(Not run)
```

regressor_parse_example_spec	<i>Generates Parsing Spec for TensorFlow Example to be Used with Regressors</i>
------------------------------	---

Description

If users keep data in `tf$Example` format, they need to call `tf$parse_example` with a proper feature spec. There are two main things that this utility helps:

- Users need to combine parsing spec of features with labels and weights (if any) since they are all parsed from same `tf$Example` instance. This utility combines these specs.
- It is difficult to map expected label by a regressor such as `dnn_regressor` to corresponding `tf$parse_example` spec. This utility encodes it by getting related information from users (key, dtype).

Usage

```
regressor_parse_example_spec(
    feature_columns,
    label_key,
    label_dtype = tf$float32,
    label_default = NULL,
    label_dimension = 1L,
    weight_column = NULL
)
```

Arguments

<code>feature_columns</code>	An iterable containing all feature columns. All items should be instances of classes derived from <code>_FeatureColumn</code> .
<code>label_key</code>	A string identifying the label. It means <code>tf\$Example</code> stores labels with this key.
<code>label_dtype</code>	A <code>tf\$dtype</code> identifies the type of labels. By default it is <code>tf\$float32</code> .
<code>label_default</code>	used as label if <code>label_key</code> does not exist in given <code>tf\$Example</code> . By default <code>default_value</code> is none, which means <code>tf\$parse_example</code> will error out if there is any missing label.
<code>label_dimension</code>	Number of regression targets per example. This is the size of the last dimension of the labels and logits Tensor objects (typically, these have shape <code>[batch_size, label_dimension]</code>).
<code>weight_column</code>	A string or a <code>_NumericColumn</code> created by <code>column_numeric</code> defining feature column representing weights. It is used to down weight or boost examples during training. It will be multiplied by the loss of the example. If it is a string, it is used as a key to fetch weight tensor from the features. If it is a <code>_NumericColumn</code> , raw tensor is fetched by key <code>weight_column\$key</code> , then <code>weight_column\$normalizer_fn</code> is applied on it to get weight tensor.

Value

A dict mapping each feature key to a `FixedLenFeature` or `VarLenFeature` value.

Raises

- `ValueError`: If label is used in `feature_columns`.
- `ValueError`: If `weight_column` is used in `feature_columns`.
- `ValueError`: If any of the given `feature_columns` is not a `_FeatureColumn` instance.
- `ValueError`: If `weight_column` is not a `_NumericColumn` instance.
- `ValueError`: if `label_key` is `NULL`.

See Also

Other parsing utilities: [classifier_parse_example_spec\(\)](#)

run_config	<i>Run Configuration</i>
------------	--------------------------

Description

This class specifies the configurations for an Estimator run.

Usage

```
run_config()
```

See Also

Other run_config methods: [task_type\(\)](#)

Examples

```
## Not run:
config <- run_config()

# Get the properties of the config
names(config)

# Change the mutable properties of the config
config <- config$replace(tf_random_seed = 11L, save_summary_steps = 12L)

# Print config as key value pairs
print(config)

## End(Not run)
```

session_run_args	<i>Create Session Run Arguments</i>
------------------	-------------------------------------

Description

Create a set of session run arguments. These are used as the return values in the `before_run(context)` callback of a [session_run_hook\(\)](#), for requesting the values of specific tensor in the `after_run(context, values)` callback.

Usage

```
session_run_args(...)
```

Arguments

... A set of tensors or operations.

See Also

[session_run_hook\(\)](#)

session_run_hook

Create Custom Session Run Hooks

Description

Create a set of session run hooks, used to record information during training of an estimator. See **Details** for more information on the various hooks that can be defined.

Usage

```
session_run_hook(
  begin = function() {
  },
  after_create_session = function(session, coord) {
  },
  before_run = function(context) {
  },
  after_run = function(context, values) {
  },
  end = function(session) {
  }
)
```

Arguments

begin	function(): An R function, to be called once before using the session.
after_create_session	function(session, coord): An R function, to be called once the new TensorFlow session has been created.
before_run	function(run_context): An R function to be called before a run.
after_run	function(run_context, run_values): An R function to be called after a run.
end	function(session): An R function to be called at the end of the session.

Typically, you'll want to define a before_run() hook that defines the set of tensors you're interested in for a particular run, and then you'll use the resulting values of those tensors in your after_run() hook. The tensors requested in your before_run() hook will be made available as part of the second argument in the after_run() hook (the values argument).

task_type

*Task Types***Description**

This constant class gives the constant strings for available task types used in `run_config`.

Usage

```
task_type()
```

See Also

Other `run_config` methods: [run_config\(\)](#)

Examples

```
## Not run:
task_type()$MASTER

## End(Not run)
```

tfestimators

*High-level Estimator API in TensorFlow for R***Description**

This library provides an R interface to the **Estimator** API inside TensorFlow that's designed to streamline the process of creating, evaluating, and deploying general machine learning and deep learning models.

Details

TensorFlow is an open source software library for numerical computation using data flow graphs. Nodes in the graph represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) communicated between them. The flexible architecture allows you to deploy computation to one or more CPUs or GPUs in a desktop, server, or mobile device with a single API.

The **TensorFlow API** is composed of a set of Python modules that enable constructing and executing TensorFlow graphs. The tensorflow package provides access to the complete TensorFlow API from within R.

For additional documentation on the tensorflow package see <https://tensorflow.rstudio.com>

train-evaluate-predict

Base Documentation for train, evaluate, and predict.

Description

Base Documentation for train, evaluate, and predict.

Arguments

- | | |
|-----------------|--|
| input_fn | An input function, typically generated by the input_fn() helper function. |
| hooks | A list of R functions, to be used as callbacks inside the training loop. By default, <code>hook_history_saver(every_n_step = 10)</code> and <code>hook_progress_bar()</code> will be attached if not provided to save the metrics history and create the progress bar. |
| checkpoint_path | The path to a specific model checkpoint to be used for prediction. If NULL (the default), the latest checkpoint in <code>model_dir</code> is used. |

train.tf_estimator *Train an Estimator*

Description

Train an estimator on a set of input data provides by the `input_fn()`.

Usage

```
## S3 method for class 'tf_estimator'
train(
  object,
  input_fn,
  steps = NULL,
  hooks = NULL,
  max_steps = NULL,
  saving_listeners = NULL,
  ...
)
```

Arguments

<code>object</code>	A TensorFlow estimator.
<code>input_fn</code>	An input function, typically generated by the <code>input_fn()</code> helper function.
<code>steps</code>	The number of steps for which the model should be trained on this particular <code>train()</code> invocation. If <code>NULL</code> (the default), this function will either train forever, or until the supplied <code>input_fn()</code> has provided all available data.
<code>hooks</code>	A list of R functions, to be used as callbacks inside the training loop. By default, <code>hook_history_saver(every_n_step = 10)</code> and <code>hook_progress_bar()</code> will be attached if not provided to save the metrics history and create the progress bar.
<code>max_steps</code>	The total number of steps for which the model should be trained. If set, <code>steps</code> must be <code>NULL</code> . If the estimator has already been trained a total of <code>max_steps</code> times, then no training will be performed.
<code>saving_listeners</code>	(Available since TensorFlow v1.4) A list of <code>CheckpointSaverListener</code> objects used for callbacks that run immediately before or after checkpoint savings.
<code>...</code>	Optional arguments, passed on to the estimator's <code>train()</code> method.

Value

A `data.frame` of the training loss history.

See Also

Other custom estimator methods: `estimator()`, `estimator_spec()`, `evaluate.tf_estimator()`, `export_savedmodel.tf_estimator()`, `predict.tf_estimator()`

`train_and_evaluate.tf_estimator`*Train and evaluate the estimator.*

Description

(Available since TensorFlow v1.4)

Usage

```
## S3 method for class 'tf_estimator'  
train_and_evaluate(object, train_spec, eval_spec, ...)
```

Arguments

<code>object</code>	An estimator object to train and evaluate.
<code>train_spec</code>	A <code>TrainSpec</code> instance to specify the training specification.
<code>eval_spec</code>	A <code>EvalSpec</code> instance to specify the evaluation and export specification.
<code>...</code>	Not used.

Details

This utility function trains, evaluates, and (optionally) exports the model by using the given estimator. All training related specification is held in `train_spec`, including training `input_fn` and training max steps, etc. All evaluation and export related specification is held in `eval_spec`, including evaluation `input_fn`, steps, etc.

This utility function provides consistent behavior for both local (non-distributed) and distributed configurations. Currently, the only supported distributed training configuration is between-graph replication.

Overfitting: In order to avoid overfitting, it is recommended to set up the training `input_fn` to shuffle the training data properly. It is also recommended to train the model a little longer, say multiple epochs, before performing evaluation, as the input pipeline starts from scratch for each training. It is particularly important for local training and evaluation.

Stop condition: In order to support both distributed and non-distributed configuration reliably, the only supported stop condition for model training is `train_spec.max_steps`. If `train_spec.max_steps` is `NULL`, the model is trained forever. *Use with care* if model stop condition is different. For example, assume that the model is expected to be trained with one epoch of training data, and the training `input_fn` is configured to throw `OutOfRangeError` after going through one epoch, which stops the `Estimator.train`. For a three-training-worker distributed configuration, each training worker is likely to go through the whole epoch independently. So, the model will be trained with three epochs of training data instead of one epoch.

Raises

- `ValueError`: if environment variable `TF_CONFIG` is incorrectly set.

<code>train_spec</code>	<i>Configuration for the train component of <code>train_and_evaluate</code></i>
-------------------------	---

Description

`TrainSpec` determines the input data for the training, as well as the duration. Optional hooks run at various stages of training.

Usage

```
train_spec(input_fn, max_steps = NULL, hooks = NULL)
```

Arguments

<code>input_fn</code>	Training input function returning a tuple of: • features - Tensor or dictionary of string feature name to Tensor. • labels - Tensor or dictionary of Tensor with labels.
<code>max_steps</code>	Positive number of total steps for which to train model. If <code>NULL</code> , train forever. The training <code>input_fn</code> is not expected to generate <code>OutOfRangeError</code> or <code>StopIteration</code> exceptions.
<code>hooks</code>	List of session run hooks to run on all workers (including chief) during training.

<code>variable_names_values</code>	<i>Get variable names and values associated with an estimator</i>
------------------------------------	---

Description

These helper functions extract the names and values of variables in the graphs associated with trained estimator models.

Usage

```
variable_names(object)
```

```
variable_value(object, variable = NULL)
```

Arguments

object	A trained estimator model.
variable	(Optional) Names of variables to extract as a character vector. If not specified, values for all variables are returned.

Value

For `variable_names()`, a vector of variable names. For `variable_values()`, a named list of variable values.
