

Package ‘LongCART’

January 20, 2025

Type Package

Title Recursive Partitioning for Longitudinal Data and Right Censored
Data Using Baseline Covariates

Version 3.2

Date 2022-05-17

Author Madan G Kundu

Maintainer Madan G Kundu <madan_g.kundu@yahoo.com>

Depends R (>= 3.4.0), nlme, rpart, survival, magic, survminer

Imports Formula

Description Constructs tree for continuous longitudinal data and survival data using baseline covariates as partitioning variables according to the 'LongCART' and 'SurvCART' algorithm, respectively. Later also included functions to calculate conditional power and predictive power of success based on interim results and probability of success for a prospective trial.

ACTG175

Converted AIDS Clinical Trials Group Study 175 (source: speff2trial package)

Description

ACTG 175 was a randomized clinical trial to compare monotherapy with zidovudine or didanosine with combination therapy with zidovudine and didanosine or zidovudine and zalcitabine in adults infected with the human immunodeficiency virus type I whose CD4 T cell counts were between 200 and 500 per cubic millimeter.

Usage

```
data(ACTG175)
```

Format

A data frame with 6417 observations from 2139 patients on the following 24 variables.

pidnum patient ID number
age age in years at baseline
wtkg weight in kg at baseline
hemo hemophilia (0=no, 1=yes)
homo homosexual activity (0=no, 1=yes)
drugs history of intravenous drug use (0=no, 1=yes)
karnof Karnofsky score (on a scale of 0-100)
oprior non-zidovudine antiretroviral therapy prior to initiation of study treatment (0=no, 1=yes)
z30 zidovudine use in the 30 days prior to treatment initiation (0=no, 1=yes)
zprior zidovudine use prior to treatment initiation (0=no, 1=yes)
preanti number of days of previously received antiretroviral therapy
race race (0=white, 1=non-white)
gender gender (0=female, 1=male)

str2 antiretroviral history (0=naive, 1=experienced)
strat antiretroviral history stratification (1:antiretroviral naive, 2:greater than 1 but less than 52 weeks of prior antiretroviral therapy, 3: greater than 52 weeks)
symptom symptomatic indicator (0=asymptomatic, 1=symptomatic)
treat treatment indicator (0=zidovudine only, 1=other therapies)
offtrt indicator of off-treatment before 96 weeks (0=no,1=yes)
r missing CD4 T cell count at 96 weeks (0=missing, 1=observed)
cens indicator of observing the event in days
days number of days until the first occurrence of: (i) a decline in CD4 T cell count of at least 50 (ii) an event indicating progression to AIDS, or (iii) death.
arms treatment arm (0=zidovudine, 1=zidovudine and didanosine, 2=zidovudine and zalcitabine, 3=didanosine)
time time in weeks
cd4 CD4 T cell count

GBSG2

German Breast Cancer Study Group 2 (source: TH.data package)

Description

A data frame containing the observations from the GBSG2 study.

Usage

```
data(GBSG2)
```

Format

A data frame with 686 observations on the following 10 variables.

horTh hormonal therapy, a factor with levels no yes
age age in years
menostat menopausal status, a factor with levels Pre Post
tsize tumor size (in mm)
tgrade an ordered factor with levels I < II < III
pnodes number of positive nodes
progrec progesterone receptor (in fmol).
estrec estrogen receptor (in fmol).
time recurrence free survival time (in days).
cens censoring indicator (0- censored, 1- event).

KMPlot

KM plot for SurvCART object

Description

Generates KM plot for sub-groups (i.e., terminal nodes) associated with survival tree generated by SurvCART()

Usage

```
KMPlot(x, type = 1, overlay=TRUE, conf.type="log-log", mfrw=NULL, ...)
```

Arguments

x	a fitted object of class "SurvCART", containing a survival tree.
type	1 for KM plot of survival probabilities, 2 for KM plot of censoring probabilities
overlay	Logical inputs (TRUE or FALSE) whether the KM plots for different subgroups will be overlaid in the same plot or separate plots to be generated
conf.type	One of none, plain, log, or log-log. The first option causes confidence intervals not to be generated. This input is ignored when overlay=TRUE.
mfrw	Desired frame for fitting multiple plots. Default option is to include plots for all subgroups in the same frame. This input is ignored when overlay=TRUE.
...	arguments to be passed to or from other methods.

```

Description

Recursive partitioning for linear mixed effects model with continuous univariate response variables per LonCART algorithm based on baseline partitioning variables (Kundu and Harezlak, 2019).

Usage

```
LongCART(data, patid, fixed, gvars, tgvars, minsplit=40,
          minbucket=20, alpha=0.05, coef.digits=2, print.lme=FALSE)
```

Arguments

data	name of the dataset. It must contain variable specified for patid (indicating subject id), all the variables specified in the formula and the baseline partitioning variables.
------	--

patid	name of the subject id variable.
fixed	a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right. Model with -1 to the end of right side indicates no intercept. For model with no fixed effect beyond intercept, please specify only 1 right to the ~ operator.
gvars	list of partitioning variables of interest. Value of these variables should not change over time. Regarding categorical variables, only numerically coded categorical variables should be specified. For nominal categorical variables or factors, please first create corresponding dummy variable(s) and then pass through gvars.
tgvars	types (categorical or continuous) of partitioning variables specified in gvar. For each of continuous partitioning variables, specify 1 and for each of the categorical partitioning variables, specify 0. Length of tgvars should match to the length of gvars
minsplit	the minimum number of observations that must exist in a node in order for a split to be attempted.
minbucket	the minimum number of observations in any terminal node.
alpha	alpha (i.e., nominal type I error) level for parameter instability test
coef.digits	decimal points for displaying coefficients in the tree structure.
print.lme	if TRUE, then summary of fitted model from lme() will be printed for each node.

Details

Construct regression tree based on heterogeneity in linear mixed effects models of following type:
 $Y_{-i}(t) = W_{-i}(t)\theta + b_{-i} + \epsilon_{it}$ where $W_{-i}(t)$ is the design matrix, θ is the parameter associated with $W_{-i}(t)$ and b_{-i} is the random intercept. Also, $\epsilon_{it} \sim N(0, \sigma^2)$ and $b_{-i} \sim N(0, \sigma_u^2)$.

Value

Treeout	contains summary information of tree fitting for each terminal nodes and non-terminal nodes. Columns of Treeout include "ID", the (unique) node numbers that follow a binary ordering indexed by node depth, n, the number of observations reaching the node, yval, the fitted model of the response at the node, var, a factor giving the names of the variables used in the split at each, index, the cut-off value of splitting variable for binary partitioning, p (Instability), the p-value for parameter instability test for the splitting variable, loglik, the log-likelihood of the node, improve, the improvement in deviance given by this split, and Terminal, indicator (True or False) of terminal node.
p	number of fixed parameters
AIC.tree	AIC of the tree-structured model
AIC.root	AIC at the root node (i.e., without tree structure)
improve.AIC	improvement in AIC due to tree structure (AIC.tree - AIC.root)
logLik.tree	log-likelihood of the tree-structured model

<code>logLik.root</code>	log-likelihood at the root node (i.e., without tree structure)
<code>Deviance</code>	$2*(\text{logLik.root} - \text{logLik.tree})$
<code>LRT.df</code>	degrees of freedom for likelihood ratio test comparing tree-structured model with the model at root node.
<code>LRT.p</code>	p-value for likelihood ratio test comparing tree-structured model with the model at root node.
<code>nodelab</code>	List of subgroups or terminal nodes with their description
<code>varnam</code>	List of splitting variables
<code>data</code>	the dataset originally supplied
<code>patid</code>	the patid variable originally supplied
<code>fixed</code>	the fixed part of the model originally supplied
<code>frame</code>	rpart compatible object
<code>splits</code>	rpart compatible object
<code>cptable</code>	rpart compatible object
<code>functions</code>	rpart compatible object

```

plot	<i>Plot an SurvCART or LongCART Object</i>
------	--

Description

Plots an SurvCART or LongCART object on the current graphics device.

Usage

```
## S3 method for class 'SurvCART'
plot(x, uniform = FALSE, branch = 1, compress = FALSE,
      nspace = branch, margin = 0, minbranch = 0.3, ...)
## S3 method for class 'LongCART'
plot(x, uniform = FALSE, branch = 1, compress = FALSE,
      nspace = branch, margin = 0, minbranch = 0.3, ...)
```

Arguments

- x a fitted object of class "SurvCART", containing a survival tree or "LongCART", containing a longitudinal tree.
- uniform similar to plot.rpart; if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
- branch similar to plot.rpart; controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
- compress similar to plot.rpart; if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree.
- nspace similar to plot.rpart; the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of branch.
- margin similar to plot.rpart; an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
- minbranch similar to plot.rpart; set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform=TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
- ... arguments to be passed to or from other methods.

Details

This function is a method for the generic function *plot*, for objects of class *SurvCART*. The y-coordinate of the top node of the tree will always be 1.

Value

The coordinates of the nodes are returned as a list, with components *x* and *y*.

PoS	<i>Probability of trial and clinical success for a prospective trial using normal-normal approximation</i>
-----	--

Description

This function can be used to determine probability of trial success and clinical success based on the prior distribution for each of continuous, binary and time-to-event endpoints. The calculation is carried out assuming normal distribution for estimated parameter and normal prior distribution.

Usage

```
PoS(type, nsamples, null.value = NULL, alternative = "greater",
    N = NULL, D = NULL, a = 1,
    succ.crit = "trial", Z.crit.final = 1.96, alpha.final = 0.025,
    clin.succ.threshold = NULL, se.exp = NULL,
    meandiff.prior = NULL, mean.prior = NULL, sd.prior = NULL,
    propdiff.prior = NULL, prop.prior = NULL, hr.prior = NULL, D.prior = NULL)
```

Arguments

type	Type of the endpoint. It could be cont for continuous, bin for binary and surv for survival endpoint.
nsamples	Number of samples. For continuous and binary case, it can be 1 or 2. For survival endpoint, it can be only 2.
null.value	The specified value under null hypothesis. Default is 0 for continuous and binomial case and 1 for survival case.
alternative	Direction of alternate hypothesis. Can be "greater" or "less". Default is "less" for test of HR and "greater" otherwise.
N	Total sample size at final analysis. Cannot be missing for continuous and binary endpoint.
D	Total number of events at final analysis. Cannot be missing for survival endpoint.
a	Allocation ratio in two sample case.
succ.crit	Specify "trial" for trial success (i.e., null hypothesis is rejected at final analysis) or "clinical" for clinical success (i.e., estimated value at the final analysis is greater than clinically meaningful value as specified under clin.succ.threshold.)
Z.crit.final	The rejection boundary at final analysis in Z-value scale. Either alpha.final or Z.crit.final must be specified when determining trial success.
alpha.final	The rejection boundary at final analysis in alpha (1-sided) scale (e.g., 0.025). Either alpha.final or Z.crit.final must be specified when determining trial success.
clin.succ.threshold	Clinically meaningful value. Required when succ.crit="clinical".

<code>se.exp</code>	Expected standard error to be observed in the study. Must be specified in continuous case and two-sample binary case.
<code>meandiff.prior</code>	Mean value of prior distribution for mean difference. Relevant for two-sample continuous case.
<code>mean.prior</code>	Mean value of prior distribution for mean. Relevant for one-sample continuous case.
<code>sd.prior</code>	Standard deviation of prior distribution for mean difference (2-sample continuous case) or mean (1-sample continuous case) or prop (2-sample binary case) or difference of proportion (1-sample binary case) or log(HR) (2 sample survival case).
<code>propdiff.prior</code>	Mean value of prior distribution for difference in proportion. Relevant for two-sample binomial case.
<code>prop.prior</code>	Mean value of prior distribution for proportion. Relevant for one-sample binomial case.
<code>hr.prior</code>	Mean value of prior distribution for hazards ratio (HR). Relevant for two-sample survival case.
<code>D.prior</code>	Ignored if <code>sd.prior</code> is specified. If <code>sd.prior</code> is not specified then <code>sd.prior</code> is determined as $2/D.prior$. Relevant for two-sample survival case.

Details

This function can be used to determine probability of success (PoS) for a prospective trial for each of continuous (one-sample or two-samples), binary (one-sample or two-samples) and time-to-event endpoints (two-samples). The PoS is calculated based on the prior distribution and expected standard error in the estimate in trial. The calculation PoS is carried out assuming normal distribution for estimated parameter and normal prior distribution. This function can be used to determine clinical success (`succ.crit="clinical"`) and trial success (`succ.crit="trial"`). For clinical success, `clin.succ.threshold` must be specified. For trial success, `Z.crit.final` or `alpha.final` must be specified.

```

predict*Predicts according to the fitted SurvCART or LongCART tree***Description**

Predicts according to the fitted SurvCART or LongCART tree.

Usage

```

## S3 method for class 'SurvCART'
predict(object, newdata, ...)
## S3 method for class 'LongCART'
predict(object, newdata, patid, ...)

```

Arguments

- | | |
|---------|---|
| object | a fitted object of class "SurvCART", containing a survival tree, or class "LongCART", containing a longitudinal tree. |
| newdata | The dataset for prediction. |

patid	Variable name containing patient id in the new dataset. Must for prediction based on LongCART object
...	Please disregard.

Details

For prediction based on "SurvCART" algorithm, the predicted dataset includes the terminal node id the observation belongs to, and the median event and censoring times of the terminal id.

For prediction based on "LongCART" algorithm, the predicted dataset includes the terminal node id the observation belongs to, the fitted profile, and the predicted value based on the fitted profile. Note that the predicted value does not consider the random effects.

Value

For prediction based on "SurvCART" algorithm, the dataset adds to the following variables in the new dataset:

node	Terminal node id the observation belongs to
median.T	Median event time of the terminal node id the observation belongs to
median.C	Median censoring time of the terminal node id the observation belongs to
Q1.T	First quartile for event time of the terminal node id the observation belongs to
Q1.C	First quartile for censoring time of the terminal node id the observation belongs to
Q3.T	Third quartile for event time of the terminal node id the observation belongs to
Q3.C	Third quartile for censoring time of the terminal node id the observation belongs to

For prediction based on LongCART algorithm, the dataset adds to the following variables in the new dataset:

node.id	Terminal node id the observation belongs to
profile	The fitted profile of the terminal node id the observation belongs to
predval	predicted value based on the fitted profile profile

```

ProfilePlot

Population level longitudinal profile plot for sub-groups

Description

Generates population level longitudinal profile plot for each of sub-groups (i.e., terminal nodes) associated with longitudinal tree generated by LongCART()

Usage

```
ProfilePlot(x, timevar, timevar.power=NULL, covariate.val=NULL,
            xlab=NULL, ylab=NULL, sg.title=4, mfrom=NULL, ...)
```

Arguments

<code>x</code>	a fitted object of class "LongCART", containing a longitudinal tree.
<code>timevar</code>	Specify the variable name containing time information in the dataset that was used to fit LongCART object
<code>timevar.power</code>	Mandatory when the fixed part of the fitted model contains term as time with power not equal to 1. For example, if fixed part of the model is $t + \text{sqrt}(t) + \text{cov1}$, then specify <code>c(1, 0.5, NA)</code> . If fixed part of the model is $t + t^2 + \text{cov1}$, then specify <code>c(1, 2, NA)</code> .
<code>covariate.val</code>	Specify the covariate values for generation of longitudinal profile plot. In the longitudinal profile plot, only time can vary and therefore, and therefore the value for the other covariates are fixed at constant value. This is not needed if the longitudinal model does not contain additional covariate(s). By default, the covariates values are specified at median value over all the datapoint (not at the subject level). For example, if the fixed part of the model is $t + \text{cov1}$, then <code>c(NA, 100)</code> sets the value of cov1 at 100. Similarly, If fixed part of the model is $t + t^2 + \text{cov1}$, then <code>c(NA, NA, 100)</code> would be acceptable.
<code>xlab</code>	Optional label for X-axis
<code>ylab</code>	Optional label for Y-axis
<code>sg.title</code>	1 for sub-groups' title as <code>Sub-group=x</code> , 2 for sub-groups' title as <code>Node=x</code> , 3 for sub-groups' title as <code>Sub-group=x (Node=x)</code> , and 4 for sub-groups' title as <node number>: <node definition>.
<code>mfrw</code>	Desired frame for fitting multiple plots. Default option is to include plots for all subgroups in the same frame. This input is ignored when <code>overlay=TRUE</code> .
<code>...</code>	Graphical parameters other than <code>x</code> , <code>y</code> , <code>type</code> , <code>xlab</code> , <code>ylab</code> .

```

Description

Performs parameter stability test (Kundu and Harezlak, 2019) with categorical partitioning variable to determine whether the parameters of linear mixed effects model remains same across all distinct values of given categorical partitioning variable.

Usage

```
StabCat(data, patid, fixed, splitvar)
```

Arguments

data	name of the dataset. It must contain variable specified for patid (indicating subject id) and all the variables specified in the formula and the categorical partitioning variable of interest specified in splitvar. Note that, only numerically coded categorical variable should be specified.
patid	name of the subject id variable.
fixed	a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right. Model with -1 to the end of right side indicates no intercept. For model with no fixed effect beyond intercept, please specify only 1 right to the ~ operator.
splitvar	the categorical partitioning variable of interest. Its value should not change over time.

Details

The categorical partitioning variable of interest. Its value should not change over time.

$$Y_i(t) = W_i(t) \theta + b_i + \epsilon_{it}$$

where $W_i(t)$ is the design matrix, θ is the parameter associated with $W_i(t)$ and b_i is the random intercept. Also, $\epsilon_{it} \sim N(0, \sigma^2)$ and $b_i \sim N(0, \sigma_u^2)$. Let X be the baseline categorical partitioning variable of interest. StabCat() performs the following omnibus test

$$H_0: \theta_{(g)} = \theta_0 \text{ vs. } H_1: \theta_{(g)} \neq \theta_0, \text{ for all } g$$

where, $\theta_{(g)}$ is the true value of theta for subjects with $X=C_g$ where C_g is the any value realized by X .

Value

p It returns the p-value for parameter instability test

Author(s)

Madan Gopal Kundu <madan_g.kundu@yahoo.com>

StabCat.surv

*parameter stability test for categorical partitioning variable***Description**

Performs parameter stability test (Kundu, 2020) with categorical partitioning variable to determine whether the parameters of exponential time-to-event distribution and exponential censoring distribution remain same across all distinct values of given categorical partitioning variable.

Usage

```
StabCat.surv(data, timevar, censorvar, splitvar,
             time.dist="exponential", cens.dist="NA", event.ind=1, print=FALSE)
```

Arguments

data	name of the dataset. It must contain variable specified for timevar (indicating follow-up times), censorvar (indicating censoring status) and the categorical partitioning variable of interest specified in splitvar . Note that, only numerically coded categorical variable should be specified.
timevar	name of the variable with follow-up times.
censorvar	name of the variable with censoring status.
time.dist	name of time-to-event distribution. It can be one of the following distributions: "exponential", "weibull", "lognormal" or "normal".
cens.dist	name of censoring distribution. It can be one of the following distributions: "exponential", "weibull", "lognormal", "normal" or "NA". If specified "NA", then parameter instability test corresponding to censoring distribution will not be performed.
event.ind	value of the censoring variable indicating event.
splitvar	the categorical partitioning variable of interest. Its value should not change over time.
print	if TRUE, then additional information including estimated parameters, score function and its variance will be printed.

Details

StabCat.surv() performs the following omnibus test

$H_0: \lambda_{\{g\}} = \lambda_0$ vs. $H_1: \lambda_{\{g\}} \neq \lambda_0$, for all g

where, $\theta_{\{g\}}$ is the true value of theta for subjects with $X=C_g$. θ includes all the parameters of time to event distribution and also parameters of censoring distribution, if specified. C_g is the any value realized by categorical partitioning variable X .

Exponential distribution: $f(t) = \lambda * \exp(-\lambda * t)$

Weibull distribution: $f(t) = \alpha * \lambda * t^{(\alpha-1)} * \exp(-\lambda * t^\alpha)$

Lognormal distribution: $f(t) = (1/t) * (1/\sqrt{2\pi\sigma^2}) * \exp[-(1/2)(\log(t)-\mu)/\sigma^2]$

Normal distribution: $f(t) = (1/\sqrt{2\pi\sigma^2}) * \exp[-(1/2)(t-\mu)/\sigma^2]$

Value

pval p-value for parameter instability test

type 1, if event times are more heterogeneous; 2, if censoring times are more heterogeneous.

StabCont	<i>parameter stability test for continuous partitioning variable</i>
----------	--

Description

Performs parameter stability test (Kundu and Harezlak, 2019) with continuous partitioning variable to determine whether the parameters of linear mixed effects model remains same across all distinct values of given continuous partitioning variable.

Usage

```
StabCont(data, patid, fixed, splitvar)
```

Arguments

data	name of the dataset. It must contain variable specified for patid (indicating subject id) and all the variables specified in the formula and the StabCont(data, fixed, splitvar)partitioning variable of interest specified in splitvar.
patid	name of the subject id variable.
fixed	a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a \sim operator and the terms, separated by + operators, on the right. Model with -1 to the end of right side indicates no intercept. For model with no fixed effect beyond intercept, please specify only 1 right to the \sim operator.
splitvar	the continuous partitioning variable of interest. It's value should not change over time.

Details

The continuous partitioning variable of interest. It's value should not change over time.

$$Y_i(t) = W_i(t)\theta + b_i + \epsilon_{it}$$

where $W_i(t)$ is the design matrix, θ is the parameter associated with $W_i(t)$ and b_i is the random intercept. Also, $\epsilon_{it} \sim N(0, \sigma^2)$ and $b_i \sim N(0, \sigma_b^2)$. Let X be the baseline continuous partitioning variable of interest. StabCont() performs the following omnibus test

$H_0 : \theta_{(g)} = \theta_0$ vs. $H_1 : \theta_{(g)} \neq \theta_0$, for all g

where, $\theta_{(g)}$ is the true value of θ for subjects with $X = C_g$ where C_g is the any value realized by X .

succ_ia	<i>Conditional power and predictive power of success based on interim results using normal-normal approximation</i>
---------	---

Description

This function can be used to determine conditional power and predictive power for trial success and clinical success based on the interim results and prior distribution for each of continuous, binary and time-to-event endpoints. The calculation is carried out assuming normal distribution for estimated parameter and normal prior distribution.

Usage

```
succ_ia(type, nsamples, null.value = NULL, alternative = NULL,
        N = NULL, n = NULL, D = NULL, d = NULL, a = 1,
        meandiff.ia = NULL, mean.ia = NULL,
        propdiff.ia = NULL, prop.ia = NULL, hr.ia = NULL,
        stderri.ia = NULL, sd.ia = NULL,
        succ.crit = "trial", Z.crit.final = 1.96,
        alpha.final = 0.025, clin.succ.threshold = NULL,
        meandiff.exp = NULL, mean.exp = NULL,
        propdiff.exp = NULL, prop.exp = NULL, hr.exp = NULL,
        meandiff.prior = NULL, mean.prior = NULL, sd.prior = NULL,
        propdiff.prior = NULL, prop.prior = NULL, hr.prior = NULL, D.prior = NULL)
```

Arguments

type	Type of the endpoint. It could be cont for continuous, bin for binary and surv for survival endpoint.
nsamples	Number of samples. For continuous and binary case, it can be 1 or 2. For survival endpoint, it can be only 2.
null.value	The specified value under null hypothesis. Default is 0 for continuous and binomial case and 1 for survival case.
alternative	Direction of alternate hypothesis. Can be "greater" or "less". Default is "less" for test of HR and "greater" otherwise.
N	Total sample size at final analysis. Cannot be missing for continuous and binary endpoint.
n	Total sample size at interim analysis. Cannot be missing for continuous and binary endpoint.
D	Total number of events at final analysis. Cannot be missing for survival endpoint.
d	Total number of events at interim analysis. Cannot be missing for survival endpoint.
a	Allocation ratio in two sample case.

<code>meandiff.ia</code>	Estimated mean difference at interim analysis. Mandatory for continuous two sample case.
<code>mean.ia</code>	Estimated mean value at interim analysis. Mandatory for continuous single sample case
<code>propdiff.ia</code>	Estimated difference in proportion at interim analysis. Mandatory for binary two sample case
<code>prop.ia</code>	Estimated proportion at interim analysis. Mandatory for binary single sample case
<code>hr.ia</code>	Estimate hazards ratio (HR) at interim analysis. Mandatory for continuous single sample case
<code>stderr.ia</code>	Standard error (SE) of estimated mean difference (in one-sample continuous case) or estimated mean (in two-sample continuous case) or estimated difference in proportion (in two-sample binary case) at interim analysis. For continuous case, if not specified, then the function attempts to estimate SE from <code>sd.ia</code> . Mandatory for two-sample binary case.
<code>sd.ia</code>	Standard deviation of estimated mean difference (in one-sample continuous case) or estimated mean (in two-sample continuous case) at interim analysis. If <code>stderr.ia</code> is specified, then the value of <code>sd.ia</code> is ignored. If <code>codestderr.ia</code> is not specified, then mandatory for continuous case.
<code>succ.crit</code>	Specify "trial" for trial success (i.e., null hypothesis is rejected at final analysis) or "clinical" for clinical success (i.e., estimated value at the final analysis is greater than clinically meaningful value as specified under <code>clin.succ.threshold</code> .)
<code>Z.crit.final</code>	The rejection boundary at final analysis in Z-value scale. Either <code>alpha.final</code> or <code>Z.crit.final</code> must be specified when determining trial success.
<code>alpha.final</code>	The rejection boundary at final analysis in alpha (1-sided) scale (e.g., 0.025). Either <code>alpha.final</code> or <code>Z.crit.final</code> must be specified when determining trial success.
<code>clin.succ.threshold</code>	Clinically meaningful value. Required when <code>succ.crit="clinical"</code> .
<code>meandiff.exp</code>	Expected mean difference in post interim data. Relevant for two-sample continuous case.
<code>mean.exp</code>	Expected mean in post interim data. Relevant for one-sample continuous case.
<code>propdiff.exp</code>	Expected difference in proportion in post interim data. Relevant for two-sample binary case.
<code>prop.exp</code>	Expected proportion in post interim data. Relevant for one-sample binary case.
<code>hr.exp</code>	Expected hazards ratio (HR) in post interim data. Relevant for two-sample survival case.
<code>meandiff.prior</code>	Mean value of prior distribution for mean difference. Relevant for two-sample continuous case.
<code>mean.prior</code>	Mean value of prior distribution for mean. Relevant for one-sample continuous case.
<code>sd.prior</code>	Standard deviation of prior distribution for mean difference (2-sample continuous case) or mean (1-sample continuous case) or prop (2-sample binary case) or difference of proportion (1-sample binary case) or log(HR) (2 sample survival case).

propdiff.prior	Mean value of prior distribution for difference in proportion. Relevant for two-sample binomial case.
prop.prior	Mean value of prior distribution for proportion. Relevant for one-sample binomial case.
hr.prior	Mean value of prior distribution for hazards ratio (HR). Relevant for two-sample survival case.
D.prior	Ignored if sd.prior is specified. If sd.prior is not specified then sd.prior is determined as 2/D.prior. Relevant for two-sample survival case.

Details

This function can be used to determine Conditional power (CP) and Predictive power or predictive probability of success (PPoS) based on the interim results for each of continuous (one-sample or two-samples), binary (one-sample or two-samples) and time-to-event endpoints (two-samples). The PPoS can be based on interim results only or using both prior information and interim results. The calculation of CP and PPoS are carried out assuming normal distribution for estimated parameter and normal prior distribution. This function can be used to determine clinical success (succ.crit="clinical") and trial success (succ.crit="trial"). For clinical success, clin.succ.threshold must be specified. For trial success, Z.crit.final or alpha.final must be specified.

In order to calculate CP and PPoS, succ.ia() should be invoked in the following form:

Continuous-two sample case (trial success):

```
succ.ia(type="cont", nsamples=2, null.value=, alternative=, N=, n=, a, meandiff.ia,
stderr.ia=, succ.crit="trial", Z.crit.final=)
```

Continuous-two sample case (clinical success):

```
succ.ia(type="cont", nsamples=2, null.value=, alternative=, N=, n=, a, meandiff.ia,
stderr.ia=, succ.crit="clinical", clin.succ.threshold=)
```

Continuous-one sample case (trial success):

```
succ.ia(type="cont", nsamples=1, null.value=, alternative=, N=, n=, mean.ia, stderr.ia=,
succ.crit="trial", Z.crit.final=)
```

Continuous-one sample case (clinical success):

```
succ.ia(type="cont", nsamples=1, null.value=, alternative=, N=, n=, mean.ia, stderr.ia=,
succ.crit="clinical", clin.succ.threshold=)
```

Binary-two sample case (trial success):

```
succ.ia(type="bin", nsamples=2, null.value=, alternative=, N=, n=, a, propdiff.ia, stderr.ia=,
succ.crit="trial", Z.crit.final=)
```

Binary-two sample case (clinical success):

```
succ.ia(type="bin", nsamples=2, null.value=, alternative=, N=, n=, a, propdiff.ia, stderr.ia=,
succ.crit="clinical", clin.succ.threshold=)
```

Binary-one sample case (trial success):

```
succ.ia(type="bin", nsamples=1, null.value=, alternative=, N=, n=, prop.ia, succ.crit="trial",
Z.crit.final=)
```

Binary-one sample case (clinical success):

```

succ.ia(type="bin", nsamples=1, null.value=, alternative=, N=, n=, prop.ia, succ.crit="clinical",
clin.succ.threshold=)

Survival-two sample case (trial success):
succ.ia(type="surv", nsamples=2, null.value=, alternative=, D=, d=, a, hr.ia, succ.crit="trial",
Z.crit.final=)

Survival-two sample case (clinical success):
succ.ia(type="surv", nsamples=2, null.value=, alternative=, D=, d=, a, hr.ia, succ.crit="clinical",
clin.succ.threshold=)

```

The conditional power is calculated assuming interim trend for post-interim data. If `meandiff.exp` (for continuous 2-samples case), `mean.exp` (for continuous 1-sample case), `propdiff.exp` (for binomial 2-samples case), `prop.exp` (for binomial 1-sample case), or `hr.exp` (for survival 2-samples case) is specified, then conditional power would be calculated using these specified value as well.

The Predictive power or Predictive probability of success (PPoS) is calculated based interim results. On top of this, it can also incorporate prior information. The prior information can be specified as follows: If `meandiff.prior`, `sd.prior` for continuous 2-samples case, `mean.prior`, `sd.prior` for continuous 1-sample case, `propdiff.prior`, `sd.prior` for binomial 2-samples case, `prop.prior`, `sd.prior` for binomial 1-sample case, and `hr.exp`, `sd.prior` (or, `hr.exp`, `D.prior`) for survival 2-samples case.

```

Description

This function can be used to determine predictive power for trial success and clinical success based on the interim results and beta prior distribution for test of population proportion.

Usage

```
succ_ia_betabinom_one(N, n, x,
                      null.value = 0, alternative = "greater",
                      test="z", correct=TRUE,
                      succ.crit = "trial", Z.crit.final = 1.96,
                      alpha.final = 0.025, clin.succ.threshold = NULL,
                      a = 1, b = 1)
```

Arguments

N	Sample size at final analysis. Cannot be missing.
n	Sample size at interim analysis. Cannot be missing.
x	Number of observed response at interim analysis. Cannot be missing.
null.value	The specified value under null hypothesis. Default is 0.
alternative	Direction of alternate hypothesis. Can be "greater" or "less".
test	Statistical test. Default is "z" for Z test. For Exact binomial test, specify "exact".
correct	A logical indicating whether Yates' continuity correction should be applied where possible. Applies to approximate Z-test only.
succ.crit	Specify "trial" for trial success (i.e., null hypothesis is rejected at final analysis) or "clinical" for clinical success (i.e., estimated value at the final analysis is greater than clinically meaningful value as specified under <code>clin.succ.threshold</code> .)
Z.crit.final	The rejection boundary at final analysis in Z-value scale. Either <code>alpha.final</code> or <code>Z.crit.final</code> must be specified when determining trial success.
alpha.final	The rejection boundary at final analysis in alpha (1-sided) scale (e.g., 0.025). Either <code>alpha.final</code> or <code>Z.crit.final</code> must be specified when determining trial success.
clin.succ.threshold	Clinically meaningful value. Required when <code>succ.crit="clinical"</code> .
a	Value of a corresponding to Beta(a, b) prior for proportion.
b	Value of b corresponding to Beta(a, b) prior for proportion.

Details

This function can be used to determine Predictive power or predictive probability of success (PPoS) based on the interim results for testing of population proportion. The calculation of PoS is carried out assuming beta prior distributions for proportion. This function can be used to determine clinical success (`succ.crit="clinical"`) and trial success (`succ.crit="trial"`). For clinical success, `clin.succ.threshold` must be specified. For trial success, `Z.crit.final` or `alpha.final` must be specified.

    a = 1, b=1)
```

succ_ia_betabinom_two *Determines predictive power of success based on interim results and beta priors for two-sample binary data*

Description

This function can be used to determine predictive power for trial success and clinical success based on the interim results and beta prior distribution for test of difference of two proportions.

Usage

```
succ_ia_betabinom_two(N.trt, N.con,
    n.trt, x.trt, n.con, x.con,
    alternative = "greater", test = "z",
    succ.crit = "trial", Z.crit.final = 1.96,
    alpha.final = 0.025, clin.succ.threshold = NULL,
    a.trt = 1, b.trt = 1, a.con = 1, b.con = 1)
```

Arguments

N.trt	Sample size in treatment arm at final analysis. Cannot be missing.
N.con	Sample size in control arm at final analysis. Cannot be missing.
n.trt	Sample size in treatment arm at interim analysis. Cannot be missing.
x.trt	Number of observed response in treatment arm at interim analysis. Cannot be missing.
n.con	Sample size in control arm at interim analysis. Cannot be missing.
x.con	Number of observed response in control arm at interim analysis. Cannot be missing.
alternative	Direction of alternate hypothesis. Can be "greater" or "less".
test	Statistical test. Default is "z" for Z test. For Fisher's exact test, specify "fisher".
succ.crit	Specify "trial" for trial success (i.e., null hypothesis is rejected at final analysis) or "clinical" for clinical success (i.e., estimated value at the final analysis is greater than clinically meaningful value as specified under clin.succ.threshold.)
Z.crit.final	The rejection boundary at final analysis in Z-value scale. Either alpha.final or Z.crit.final must be specified when determining trial success.
alpha.final	The rejection boundary at final analysis in alpha (1-sided) scale (e.g., 0.025). Either alpha.final or Z.crit.final must be specified when determining trial success.
clin.succ.threshold	Clinically meaningful value. Required when succ.crit="clinical".
a.trt	Value of a corresponding to Beta(a, b) prior in treatment arm.
b.trt	Value of b corresponding to Beta(a, b) prior in treatment arm.
a.con	Value of a corresponding to Beta(a, b) prior for proportion in control arm.
b.con	Value of b corresponding to Beta(a, b) prior for proportion in control arm.

Details

This function can be used to determine Predictive power or predictive probability of success (PPoS) based on the interim results for comparison of two proportions. The calculation of PoS is carried out assuming beta prior distributions for proportions in both treatment and control arms. This function can be used to determine clinical success (succ.crit="clinical") and trial success (succ.crit="trial"). For clinical success, clin.succ.threshold must be specified. For trial success, Z.crit.final or alpha.final must be specified.

```

SurvCART*Survival CART with time to event response via binary partitioning*

Description

Recursive partitioning for linear mixed effects model with survival data per SurvCART algorithm based on baseline partitioning variables (Kundu, 2020).

Usage

```
SurvCART(data, patid, timevar, censorvar, gvars, tgvars,
          time.dist="exponential", cens.dist="NA", event.ind=1,
          alpha=0.05, minsplit=40, minbucket=20, quantile=0.50, print=FALSE)
```

Arguments

data	name of the dataset. It must contain variable specified for patid (indicating subject id), all the variables specified in the formula and the baseline partitioning variables.
patid	name of the subject id variable.
timevar	name of the variable with follow-up times.
censorvar	name of the variable with censoring status.
gvars	list of partitioning variables of interest. Value of these variables should not change over time. Regarding categorical variables, only numerically coded categorical variables should be specified. For nominal categorical variables or factors, please first create corresponding dummy variable(s) and then pass through gvars .
tgvars	types (categorical or continuous) of partitioning variables specified in gvars . For each of continuous partitioning variables, specify 1 and for each of the categorical partitioning variables, specify 0. Length of tgvars should match to the length of gvars
time.dist	name of time-to-event distribution. It can be one of the following distributions: "exponential", "weibull", "lognormal" or "normal".
cens.dist	name of censoring distribution. It can be one of the following distributions: "exponential", "weibull", "lognormal", "normal" or "NA". If specified "NA", then parameter instability test corresponding to censoring distribution will not be performed.
event.ind	value of the censoring variable indicating event.
alpha	alpha (i.e., nominal type I error) level for parameter instability test
minsplit	the minimum number of observations that must exist in a node in order for a split to be attempted.
minbucket	the minimum number of observations in any terminal node.
quantile	The quantile to be displayed in the visualization of tree through <code>plot.SurvCART()</code> or <code>plot()</code> .

print if TRUE, then summary such as number of subjects at risk, number of events, median event time and median censoring time model will be printed for each node.

Details

Construct survival tree based on heterogeneity in time-to-event and censoring distributions.

Exponential distribution: $f(t)=\lambda e^{-\lambda t}$

Weibull distribution: $f(t)=\alpha\lambda t^{\alpha-1}e^{-\lambda t^\alpha}$

Lognormal distribution: $f(t)=\frac{1}{t\sqrt{2\pi\sigma^2}}e^{-\frac{(ln(t)-\mu)^2}{2\sigma^2}}$

Normal distribution: $f(t)=\frac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{(t-\mu)^2}{2\sigma^2}}$

Value

Treeout	contains summary information of tree fitting for each terminal nodes and non-terminal nodes. Columns of Treeout include "ID", the (unique) node numbers that follow a binary ordering indexed by node depth, n, the number of subjects reaching the node, D, the number of events reaching the node, median.T, the median survival time at the node, median.C, the median censoring time at the node, var, splitting variable, index, the cut-off value of splitting variable for binary partitioning, p (Instability), the p-value for parameter instability test for the splitting variable, loglik, the log-likelihood at the node, AIC, the AIC at the node, improve, the improvement in deviance given by this split, and Terminal, indicator (True or False) of terminal node.
logLik.tree	log-likelihood of the tree-structured model, based on Cox model including sub-groups as covariates
logLik.root	log-likelihood at the root node (i.e., without tree structure), based on Cox model without any covariate
AIC.tree	AIC of the tree-structured model, based on Cox model including sub-groups as covariates
AIC.root	AIC at the root node (i.e., without tree structure), based on Cox model without any covariate
nodelab	List of subgroups or terminal nodes with their description
varnam	List of splitting variables
ds	the dataset originally supplied
event.ind	value of the censoring variable indicating event.
timevar	name of the variable with follow-up times
censorvar	name of the variable with censoring status
frame	rpart compatible object
splits	rpart compatible object
ctable	rpart compatible object
functions	rpart compatible object

text

Place text on SurvCART or LongCART tree

Description

Labels the current plot of the tree generated from SurvCART or LongCART object with text.

Usage

```
## S3 method for class 'SurvCART'
text(x, splits = TRUE, all = FALSE,
     use.n = FALSE, minlength = 1L, ...)
## S3 method for class 'LongCART'
text(x, splits = TRUE, all = FALSE,
     use.n = FALSE, minlength = 1L, ...)
```

Arguments

- | | |
|-----------|--|
| x | a fitted object of class "SurvCART", containing a survival tree, or class "LongCART", containing a longitudinal tree. |
| splits | similar to text.rpart; logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split. |
| all | similar to text.rpart; Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes. |
| use.n | similar to text.rpart; Logical. If TRUE, adds n to label. |
| minlength | similar to text.rpart; the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', Larger values use abbreviations of the label names. See the labels.rpart function for details. |
| ... | arguments to be passed to or from other methods. |
