

# Package ‘adbcdrivermanager’

July 13, 2025

**Title** 'Arrow' Database Connectivity ('ADBC') Driver Manager

**Version** 0.19.0

**Description** Provides a developer-facing interface to 'Arrow' Database Connectivity ('ADBC') for the purposes of driver development, driver testing, and building high-level database interfaces for users. 'ADBC' <<https://arrow.apache.org/adbc/>> is an API standard for database access libraries that uses 'Arrow' for result sets and query parameters.

**License** Apache License (>= 2)

**Encoding** UTF-8

**RoxygenNote** 7.3.2

**Suggests** testthat (>= 3.0.0), withr

**Config/testthat/edition** 3

**Config/build/bootstrap** TRUE

**URL** <https://arrow.apache.org/adbc/current/r/adbcdrivermanager/>,  
<https://github.com/apache/arrow-adbc>

**BugReports** <https://github.com/apache/arrow-adbc/issues>

**Imports** nanoarrow (>= 0.3.0)

**NeedsCompilation** yes

**Author** Dewey Dunnington [aut, cre] (ORCID:  
<<https://orcid.org/0000-0002-9415-4582>>),  
Apache Arrow [aut, cph],

| adbc_connection_get_info  |
| <i>Connection methods</i> |

---

Description

Connection methods

Usage

```
adbc_connection_get_info(connection, info_codes = NULL)

adbc_connection_get_objects(
  connection,
  depth = 0L,
  catalog = NULL,
  db_schema = NULL,
  table_name = NULL,
  table_type = NULL,
  column_name = NULL
)

adbc_connection_get_table_schema(connection, catalog, db_schema, table_name)

adbc_connection_get_table_types(connection)

adbc_connection_read_partition(connection, serialized_partition)
```

```

adbc_connection_commit(connection)

adbc_connection_rollback(connection)

adbc_connection_cancel(connection)

adbc_connection_get_statistic_names(connection)

adbc_connection_get_statistics(
    connection,
    catalog,
    db_schema,
    table_name,
    approximate = FALSE
)

adbc_connection_quote_identifier(connection, value, ...)

adbc_connection_quote_string(connection, value, ...)

```

## Arguments

|                      |                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| connection           | An <a href="#">adbc_connection</a>                                                                                                                                                                                                                                                      |
| info_codes           | A list of metadata codes to fetch, or NULL to fetch all. Valid values are documented in the <code>adbc.h</code> header.                                                                                                                                                                 |
| depth                | The level of nesting to display. If 0, display all levels. If 1, display only catalogs (i.e., <code>catalog_schemas</code> will be null). If 2, display only catalogs and schemas (i.e., <code>db_schema_tables</code> will be null). If 3, display only catalogs, schemas, and tables. |
| catalog              | Only show tables in the given catalog. If NULL, do not filter by catalog. If an empty string, only show tables without a catalog. May be a search pattern.                                                                                                                              |
| db_schema            | Only show tables in the given database schema. If NULL, do not filter by database schema. If an empty string, only show tables without a database schema. May be a search pattern.                                                                                                      |
| table_name           | Constrain an object or statistics query for a specific table. If NULL, do not filter by name. May be a search pattern.                                                                                                                                                                  |
| table_type           | Only show tables matching one of the given table types. If NULL, show tables of any type. Valid table types can be fetched from <code>GetTableTypes</code> . Terminate the list with a NULL entry.                                                                                      |
| column_name          | Only show columns with the given name. If NULL, do not filter by name. May be a search pattern.                                                                                                                                                                                         |
| serialized_partition | The partition descriptor.                                                                                                                                                                                                                                                               |
| approximate          | If FALSE, request exact values of statistics, else allow for best-effort, approximate, or cached values. The database may return approximate values regardless, as indicated in the result. Requesting exact values may be expensive or unsupported.                                    |

|       |                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------|
| value | A string or identifier.                                                                                |
| ...   | Driver-specific options. For the default method, these are named values that are converted to strings. |

### Value

- `adb_connection_get_info()`, `adb_connection_get_objects()`, `adb_connection_get_table_types()`, and `adb_connection_read_partition()` return a [nanoarrow\\_array\\_stream](#).
- `adb_connection_get_table_schema()` returns a [nanoarrow\\_schena](#)
- `adb_connection_commit()` and `adb_connection_rollback()` return connection, invisibly.

### Examples

```
db <- adb_database_init(adb_driver_void())
con <- adb_connection_init(db)
# (not implemented by the void driver)
try(adb_connection_get_info(con, 0))
```

---

adb\_connection\_init    *Connections*

---

### Description

Connections

### Usage

```
adb_connection_init(database, ...)

adb_connection_init_default(database, options = NULL, subclass = character())

adb_connection_release(connection)

adb_connection_set_options(connection, options)

adb_connection_get_option(connection, option)

adb_connection_get_option_bytes(connection, option)

adb_connection_get_option_int(connection, option)

adb_connection_get_option_double(connection, option)
```

### Arguments

|            |                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------|
| database   | An <a href="#">adbc_database</a> .                                                                               |
| ...        | Driver-specific options. For the default method, these are named values that are converted to strings.           |
| options    | A named <code>character()</code> or <code>list()</code> whose values are converted to strings.                   |
| subclass   | An extended class for an object so that drivers can specify finer-grained control over behaviour at the R level. |
| connection | An <a href="#">adbc_connection</a>                                                                               |
| option     | A specific option name                                                                                           |

### Value

An object of class 'adbc\_connection'

### Examples

```
db <- adbc_database_init(adbc_driver_void())
adbc_connection_init(db)
```

---

adbc\_connection\_join    *Join the lifecycle of a unique parent to its child*

---

### Description

It is occasionally useful to return a connection, statement, or stream from a function that was created from a unique parent. These helpers tie the lifecycle of a unique parent object to its child such that the parent object is released predictably and immediately after the child. These functions will invalidate all references to the previous R object.

### Usage

```
adbc_connection_join(connection, database)
```

```
adbc_statement_join(statement, connection)
```

### Arguments

|            |                                                                  |
|------------|------------------------------------------------------------------|
| connection | A connection created with <a href="#">adbc_connection_init()</a> |
| database   | A database created with <a href="#">adbc_database_init()</a>     |
| statement  | A statement created with <a href="#">adbc_statement_init()</a>   |

### Value

The input, invisibly.

**Examples**

```
# Use local_adbc to ensure prompt cleanup on error;
# use join functions to return a single object that manages
# the lifecycle of all three.
stmt <- local({
  db <- local_adbc(adbc_database_init(adbc_driver_log()))

  con <- local_adbc(adbc_connection_init(db))
  adbc_connection_join(con, db)

  stmt <- local_adbc(adbc_statement_init(con))
  adbc_statement_join(stmt, con)

  adbc_xptr_move(stmt)
})

# Everything is released immediately when the last object is released
adbc_statement_release(stmt)
```

---

|                    |                  |
|--------------------|------------------|
| adbc_database_init | <i>Databases</i> |
|--------------------|------------------|

---

**Description**

Databases

**Usage**

```
adbc_database_init(driver, ...)

adbc_database_init_default(driver, options = NULL, subclass = character())

adbc_database_release(database)

adbc_database_set_options(database, options)

adbc_database_get_option(database, option)

adbc_database_get_option_bytes(database, option)

adbc_database_get_option_int(database, option)

adbc_database_get_option_double(database, option)
```

## Arguments

|          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| driver   | An <a href="#">adbc_driver()</a> .                                                                               |
| ...      | Driver-specific options. For the default method, these are named values that are converted to strings.           |
| options  | A named <code>character()</code> or <code>list()</code> whose values are converted to strings.                   |
| subclass | An extended class for an object so that drivers can specify finer-grained control over behaviour at the R level. |
| database | An <a href="#">adbc_database</a> .                                                                               |
| option   | A specific option name                                                                                           |

## Value

An object of class `adbc_database`

## Examples

```
adbc_database_init(adbc_driver_void())
```

---

|                  |                                |
|------------------|--------------------------------|
| adbc_driver_load | <i>Low-level driver loader</i> |
|------------------|--------------------------------|

---

## Description

Most users should use [adbc\\_driver\(\)](#); however, this function may be used to allow other libraries (e.g., GDAL) to access the driver loader.

## Usage

```
adbc_driver_load(
  x,
  entrypoint,
  version,
  driver,
  error,
  load_flags = adbc_load_flags()
)
```

## Arguments

|               |                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, entrypoint | An ADBC driver may be defined either as an init function or as an identifier with an entrypoint name. A driver init func must be an external pointer to a <code>DL_FUNC</code> with the type <code>AdbcDriverInitFunc</code> specified in the <code>adbc.h</code> header. |
| version       | The version number corresponding to the driver supplied                                                                                                                                                                                                                   |
| driver        | An external pointer to an <code>AdbcDriver</code>                                                                                                                                                                                                                         |
| error         | An external pointer to an <code>AdbcError</code> or <code>NULL</code>                                                                                                                                                                                                     |
| load_flags    | Integer flags generated by <a href="#">adbc_load_flags()</a>                                                                                                                                                                                                              |

**Value**

An integer ADBC status code

---

|                 |                                    |
|-----------------|------------------------------------|
| adbc_driver_log | <i>Log calls to another driver</i> |
|-----------------|------------------------------------|

---

**Description**

Useful for debugging or ensuring that certain calls occur during initialization and/or cleanup. The current logging output should not be considered stable and may change in future releases.

**Usage**

adbc\_driver\_log()

**Value**

An object of class 'adbc\_driver\_log'

**Examples**

```
drv <- adbc_driver_log()
db <- adbc_database_init(drv, key = "value")
con <- adbc_connection_init(db, key = "value")
stmt <- adbc_statement_init(con, key = "value")
try(adbc_statement_execute_query(stmt))
adbc_statement_release(stmt)
adbc_connection_release(con)
adbc_database_release(db)
```

---

|                    |                               |
|--------------------|-------------------------------|
| adbc_driver_monkey | <i>Monkey see, monkey do!</i> |
|--------------------|-------------------------------|

---

**Description**

A driver whose query results are set in advance.

**Usage**

adbc\_driver\_monkey()

**Value**

An object of class 'adbc\_driver\_monkey'

**Examples**

```
db <- adbc_database_init(adbc_driver_monkey())
con <- adbc_connection_init(db)
stmt <- adbc_statement_init(con, mtcars)
stream <- nanarrow::nanarrow_allocate_array_stream()
adbc_statement_execute_query(stmt, stream)
as.data.frame(stream$get_next())
```

---

|                  |                            |
|------------------|----------------------------|
| adbc_driver_void | <i>Create ADBC drivers</i> |
|------------------|----------------------------|

---

**Description**

Creates the R object representation of an ADBC driver, which consists of a name and an initializer function with an optional subclass to control finer-grained behaviour at the R level.

**Usage**

```
adbc_driver_void()

adbc_driver(
  x,
  entrypoint = NULL,
  ...,
  load_flags = adbc_load_flags(),
  subclass = character()
)
```

**Arguments**

|               |                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, entrypoint | An ADBC driver may be defined either as an init function or as an identifier with an entrypoint name. A driver init func must be an external pointer to a DL_FUNC with the type <code>AdbcDriverInitFunc</code> specified in the <code>adbc.h</code> header. |
| ...           | Further key/value parameters to store with the (R-level) driver object.                                                                                                                                                                                      |
| load_flags    | Integer flags generated by <a href="#">adbc_load_flags()</a>                                                                                                                                                                                                 |
| subclass      | An optional subclass for finer-grained control of behaviour at the R level.                                                                                                                                                                                  |

**Value**

An object of class 'adbc\_driver'

**Examples**

```
adbc_driver_void()
```

---

adbc\_error\_from\_array\_stream

*Get extended error information from an array stream*

---

### Description

Get extended error information from an array stream

### Usage

```
adbc_error_from_array_stream(stream)
```

### Arguments

stream            A [nanoarrow\\_array\\_stream](#)

### Value

NULL if stream was not created by a driver that supports extended error information or a list whose first element is the status code and second element is the adbc\_error object. The adbc\_error must not be accessed if stream is explicitly released.

### Examples

```
db <- adbc_database_init(adbc_driver_monkey())
con <- adbc_connection_init(db)
stmt <- adbc_statement_init(con, mtcars)
stream <- nanoarrow::nanoarrow_allocate_array_stream()
adbc_statement_execute_query(stmt, stream)
adbc_error_from_array_stream(stream)
```

---

adbc\_load\_flags

*Driver search/load options*

---

### Description

Options that indicate where to look for driver manifests. Manifests (.toml files) can be installed at the system level, the user level, and/or location(s) specified by the ADBC\_CONFIG\_PATH environment variable. See the ADBC documentation for details regarding the locations of the user and system paths on various platforms.

**Usage**

```
adbc_load_flags(  
  search_env = TRUE,  
  search_user = TRUE,  
  search_system = TRUE,  
  allow_relative_paths = TRUE  
)
```

**Arguments**

- search\_env      Search for manifest files in the directories specified by the ADBC\_CONFIG\_PATH environment variable.
- search\_user      Search for manifest files in the designated directory for user ADBC driver installs.
- search\_system   Search for manifest files in the designated directory for system ADBC driver installs.
- allow\_relative\_paths      Allow shared objects to be specified relative to the current working directory.

**Value**

An integer flag value for use in `adbc_driver()`

---

|                     |                   |
|---------------------|-------------------|
| adbc_statement_init | <i>Statements</i> |
|---------------------|-------------------|

---

**Description**

Statements

**Usage**

```
adbc_statement_init(connection, ...)  
  
adbc_statement_init_default(connection, options = NULL, subclass = character())  
  
adbc_statement_release(statement)  
  
adbc_statement_set_options(statement, options)  
  
adbc_statement_get_option(statement, option)  
  
adbc_statement_get_option_bytes(statement, option)  
  
adbc_statement_get_option_int(statement, option)  
  
adbc_statement_get_option_double(statement, option)
```

**Arguments**

|            |                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------|
| connection | An <a href="#">adbc_connection</a>                                                                               |
| ...        | Driver-specific options. For the default method, these are named values that are converted to strings.           |
| options    | A named character() or list() whose values are converted to strings.                                             |
| subclass   | An extended class for an object so that drivers can specify finer-grained control over behaviour at the R level. |
| statement  | An <a href="#">adbc_statement</a>                                                                                |
| option     | A specific option name                                                                                           |

**Value**

An object of class 'adbc\_statement'

**Examples**

```
db <- adbc_database_init(adbc_driver_void())
con <- adbc_connection_init(db)
adbc_statement_init(con)
```

---

adbc\_statement\_set\_sql\_query  
*Statement methods*

---

**Description**

Statement methods

**Usage**

```
adbc_statement_set_sql_query(statement, query)

adbc_statement_set_substrait_plan(statement, plan)

adbc_statement_prepare(statement)

adbc_statement_get_parameter_schema(statement)

adbc_statement_bind(statement, values, schema = NULL)

adbc_statement_bind_stream(statement, stream, schema = NULL)

adbc_statement_execute_query(
  statement,
  stream = NULL,
```

```

    stream_join_parent = FALSE
  )

  adbc_statement_execute_schema(statement)

  adbc_statement_cancel(statement)

```

### Arguments

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| statement          | An <a href="#">adbc_statement</a>                                              |
| query              | An SQL query as a string                                                       |
| plan               | A raw vector representation of a serialized Substrait plan.                    |
| values             | A <a href="#">nanoarrow_array</a> or object that can be coerced to one.        |
| schema             | A <a href="#">nanoarrow_schema</a> or object that can be coerced to one.       |
| stream             | A <a href="#">nanoarrow_array_stream</a> or object that can be coerced to one. |
| stream_join_parent | Use TRUE to invalidate statement and tie its lifecycle to stream.              |

### Value

- `adbc_statement_set_sql_query()`, `adbc_statement_set_substrait_plan()`, `adbc_statement_prepare()`, `adbc_statement_bind()`, `adbc_statement_bind_stream()`, and `adbc_statement_execute_query()` return statement, invisibly.
- `adbc_statement_get_parameter_schema()` returns a [nanoarrow\\_schema](#).

### Examples

```

db <- adbc_database_init(adbc_driver_void())
con <- adbc_connection_init(db)
stmt <- adbc_statement_init(con)
# (not implemented by the void driver)
try(adbc_statement_set_sql_query(stmt, "some query"))

```

---

|                |                                  |
|----------------|----------------------------------|
| adbc_xptr_move | <i>Low-level pointer details</i> |
|----------------|----------------------------------|

---

### Description

- `adbc_xptr_move()` allocates a fresh R object and moves all values pointed to by `x` into it. The original R object is invalidated by zeroing its content. This is useful when returning from a function where [lifecycle helpers](#) were used to manage the original object.
- `adbc_xptr_is_valid()` provides a means by which to test for an invalidated pointer.

**Usage**

```
adbc_xptr_move(x, check_child_count = TRUE)

adbc_xptr_is_valid(x)
```

**Arguments**

**x** An 'adbc\_database', 'adbc\_connection', 'adbc\_statement', or 'nanoarrow\_array\_stream'

**check\_child\_count** Ensures that x has a zero child count before performing the move. This should almost always be TRUE.

**Value**

- `adbc_xptr_move()`: A freshly-allocated R object identical to x
- `adbc_xptr_is_valid()`: Returns FALSE if the ADBC object pointed to by x has been invalidated.

**Examples**

```
db <- adbc_database_init(adbc_driver_void())
adbc_xptr_is_valid(db)
db_new <- adbc_xptr_move(db)
adbc_xptr_is_valid(db)
adbc_xptr_is_valid(db_new)
```

---

read\_adbc

---

*Read, write, and execute on ADBC connections*

---

**Description**

These are convenience methods useful for testing connections. Note that S3 dispatch is always on `db_or_con` (i.e., drivers may provide their own implementations).

**Usage**

```
read_adbc(db_or_con, query, ..., bind = NULL)

execute_adbc(db_or_con, query, ..., bind = NULL)

write_adbc(
  tbl,
  db_or_con,
  target_table,
  ...,
  mode = c("default", "create", "append"),
  temporary = FALSE
)
```

**Arguments**

|              |                                                                                                                                                                                                                        |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_or_con    | An <code>adbc_database</code> or <code>adbc_connection</code> . If a database, a connection will be opened. For <code>read_adbc()</code> , this connection will be closed when the resulting stream has been released. |
| query        | An SQL query                                                                                                                                                                                                           |
| ...          | Passed to S3 methods.                                                                                                                                                                                                  |
| bind         | A <code>data.frame</code> , <code>nanoarrow_array</code> , or <code>nanoarrow_array_stream</code> of bind parameters or <code>NULL</code> to skip the bind/prepare step.                                               |
| tbl          | A <code>data.frame</code> , <a href="#">nanoarrow_array</a> , or <a href="#">nanoarrow_array_stream</a> .                                                                                                              |
| target_table | A target table name to which <code>tbl</code> should be written.                                                                                                                                                       |
| mode         | One of "create", "append", or "default" (error if the schema is not compatible or append otherwise).                                                                                                                   |
| temporary    | Use <code>TRUE</code> to create a table as a temporary table.                                                                                                                                                          |

**Value**

- `read_adbc()`: A [nanoarrow\\_array\\_stream](#)
- `execute_adbc()`: `db_or_con`, invisibly.
- `write_adbc()`: `tbl`, invisibly.

**Examples**

```
# On a database, connections are opened and closed
db <- adbc_database_init(adbc_driver_log())
try(read_adbc(db, "some sql"))
try(execute_adbc(db, "some sql"))
try(write_adbc(mtcars, db, "some_table"))

# Also works on a connection
con <- adbc_connection_init(db)
try(read_adbc(con, "some sql"))
try(execute_adbc(con, "some sql"))
try(write_adbc(mtcars, con, "some_table"))
```

with\_adbc

*Cleanup helpers***Description**

Managing the lifecycle of databases, connections, and statements can be complex and error-prone. The R objects that wrap the underlying ADBC pointers will perform cleanup in the correct order if you rely on garbage collection (i.e., do nothing and let the objects go out of scope); however it is good practice to explicitly clean up these objects. These helpers are designed to make explicit and predictable cleanup easy to accomplish.

**Usage**

```
with_adbc(x, code)

local_adbc(x, .local_envir = parent.frame())
```

**Arguments**

|                           |                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | An ADBC database, ADBC connection, ADBC statement, or <code>nanoarrow_array_stream</code> returned from calls to an ADBC function. |
| <code>code</code>         | Code to execute before cleaning up the input.                                                                                      |
| <code>.local_envir</code> | The execution environment whose scope should be tied to the input.                                                                 |

**Details**

Note that you can use [adbc\\_connection\\_join\(\)](#) and [adbc\\_statement\\_join\(\)](#) to tie the lifecycle of the parent object to that of the child object. These functions mark any previous references to the parent object as released so you can still use `local` and `with` helpers to manage the parent object before it is joined. Use `stream_join_parent = TRUE` in [adbc\\_statement\\_execute\\_query\(\)](#) to tie the lifecycle of a statement to the output stream.

**Value**

- `with_adbc()` returns the result of code
- `local_adbc()` returns the input, invisibly.

**Examples**

```
# Using with_adbc():
with_adbc(db <- adbc_database_init(adbc_driver_void()), {
  with_adbc(con <- adbc_connection_init(db), {
    with_adbc(stmt <- adbc_statement_init(con), {
      # adbc_statement_set_sql_query(stmt, "SELECT * FROM foofy")
      # adbc_statement_execute_query(stmt)
      "some result"
    })
  })
})

# Using local_adbc_*(*) (works best within a function, test, or local())
local({
  db <- local_adbc(adbc_database_init(adbc_driver_void()))
  con <- local_adbc(adbc_connection_init(db))
  stmt <- local_adbc(adbc_statement_init(con))
  # adbc_statement_set_sql_query(stmt, "SELECT * FROM foofy")
  # adbc_statement_execute_query(stmt)
  "some result"
})
```
