Package 'fmeffects'

November 5, 2024

Title Model-Agnostic Interpretations with Forward Marginal Effects

Version 0.1.4

Description Create local, regional, and global explanations for any machine learning model with forward marginal effects. You provide a model and data, and 'fmeffects' computes feature effects. The package is based on the theory in: C. A. Scholbeck, G. Casalicchio, C. Molnar, B. Bischl, and C. Heumann (2022) <doi:10.48550/arXiv.2201.08837>.

fmeffects-package *fmeffects*

Description

Computes forward marginal effects (FME) for arbitrary supervised machine learning models. You provide a model and data, and 'fmeffects' gives you feature effects.

ame

Computes AMEs for every feature (or a subset of features) of a model.

Description

This is a wrapper function for AverageMarginalEffects\$new(...)\$compute(). It computes Average Marginal Effects (AME) based on Forward Marginal Effects (FME) for a model. The AME is a simple mean FME and computed w.r.t. a feature variable and a model.

Usage

ame(model, data, features = NULL, ep.method = "none")

model	The (trained) model, with the ability to predict on new data. This must be a train.formula (tidymodels), Learner (mlr3), train (caret), lm or glm object.
data	The data used for computing AMEs, must be data.frame or data.table.
features	If not NULL, a named list of the names of the feature variables for which AMEs should be computed, together with the desired step sizes. For numeric features, the step size must be a single number. For categorial features, the step size must be a character vector of category names that is a subset of the levels of the factor variable.
ep.method	String specifying the method used for extrapolation detection. One of "none" or "envelope". Defaults to "none".

Value

An AverageMarginalEffects object, with a field results containing a list of summary statistics, including

- Feature: The name of the feature.
- step.size: The step.size w.r.t. the specified feature.
- AME: The Average Marginal Effect for a step of length step.size w.r.t. the specified feature.
- SD: The standard deviation of FMEs for the specified feature and step.size.
- 0.25: The 0.25-quantile of FMEs for the specified feature and step.size.
- 0.75: The 0.75-quantile of FMEs for the specified feature and step.size.
- n: The number of observations included for the computation of the AME. This can vary for the following reasons: For categorical features, FMEs are only computed for observations where the original category is not the step.size category. For numerical features, FMEs are only computed for observations that are not extrapolation points (if ep.method is set to "envelope").

Examples

```
# Train a model:
library(mlr3verse)
library(ranger)
data(bikes, package = "fmeffects")
set.seed(123)
task = as_task_regr(x = bikes, id = "bikes", target = "count")
forest = lrn("regr.ranger")$train(task)
# Compute AMEs for all features:
## Not run:
overview = ame(model = forest, data = bikes)
summary(overview)
# Compute AMEs for a subset of features with non-default step.sizes:
overview = ame(model = forest,
               data = bikes,
               features = list(humidity = 0.1, weather = c("clear", "rain")))
summary(overview)
# Extract results:
overview$results
## End(Not run)
```

AverageMarginalEffects

R6 Class computing Average Marginal Effects (AME) based on Forward Marginal Effects (FME) for a model

Description

The AME is a simple mean FME and computed w.r.t. a feature variable and a model.

Public fields

predictor Predictor object

features vector of features for which AMEs should be computed

ep.method string specifying extrapolation detection method

results data.table with AMEs computed

computed logical specifying if compute() has been run

Methods

Public methods:

- AverageMarginalEffects\$new()
- AverageMarginalEffects\$compute()
- AverageMarginalEffects\$clone()

Method new(): Create a new AME object.

Usage:

AverageMarginalEffects\$new(model, data, features = NULL, ep.method = "none")

Arguments:

- model The (trained) model, with the ability to predict on new data. This must be a train.formula (tidymodels), Learner (mlr3), train (caret), lm or glm object.
- data The data used for computing AMEs, must be data.frame or data.table.
- features If not NULL, a named list of the names of the feature variables for which AMEs should be computed, together with the desired step sizes. For numeric features, the step size must be a single number. For categorial features, the step size must be a character vector of category names that is a subset of the levels of the factor variable.
- ep.method String specifying the method used for extrapolation detection. One of "none" or "envelope". Defaults to "none".

Returns: A new AME object.

Examples:

```
# Train a model:
library(mlr3verse)
library(ranger)
set.seed(123)
data(bikes, package = "fmeffects")
task = as_task_regr(x = bikes, id = "bikes", target = "count")
forest = lrn("regr.ranger")$train(task)
# Compute AMEs for all features:
\dontrun{
overview = AverageMarginalEffects$new(
 model = forest,
  data = bikes)$compute()
summary(overview)
# Compute AMEs for a subset of features with non-default step.sizes:
overview = AverageMarginalEffects$new(model = forest,
                                      data = bikes,
                                      features = list(humidity = 0.1,
                                     weather = c("clear", "rain")))$compute()
summary(overview)
}
```

Method compute(): Computes results, i.e., AMEs including the SD of FMEs, for an AME object.

Usage:

AverageMarginalEffects\$compute()

Returns: An AME object with results.

Examples:
Compute results:
\dontrun{
overview\$compute()
}

Method clone(): The objects of this class are cloneable with this method.

Usage:

AverageMarginalEffects\$clone(deep = FALSE)

Arguments:

deep Whether to make a deep clone.

Examples

```
## ------
## Method `AverageMarginalEffects$new`
## ------
```

Train a model:

6

bikes

```
library(mlr3verse)
library(ranger)
set.seed(123)
data(bikes, package = "fmeffects")
task = as_task_regr(x = bikes, id = "bikes", target = "count")
forest = lrn("regr.ranger")$train(task)
# Compute AMEs for all features:
## Not run:
overview = AverageMarginalEffects$new(
 model = forest,
 data = bikes)$compute()
summary(overview)
# Compute AMEs for a subset of features with non-default step.sizes:
overview = AverageMarginalEffects$new(model = forest,
                                  data = bikes,
                                  features = list(humidity = 0.1,
                                           weather = c("clear", "rain")))$compute()
summary(overview)
## End(Not run)
## ------
## Method `AverageMarginalEffects$compute`
## ------
# Compute results:
## Not run:
overview$compute()
## End(Not run)
```

bikes

Regression data of the usage of rental bikes in Washington D.C., USA

Description

This data set contains information on daily bike sharing usage in Washington, D.C. for the years 2011-2012. The target variable is count, the total number of bikes lent out to users at a specific day.

Usage

```
data(bikes)
```

Format

An object of class data. frame with 731 rows and 10 columns.

came

Details

This data frame contains the following columns:

season Season of the year year Year; 0=2011, 1=2012 holiday If a day is a public holiday (y/n) weekday Day of the week workingday If a day is aworking day (y/n) weather Weather situation temp Temperature in degrees celsius humidity Humidity (relative) windspeed Windspeed in miles per hour count Total number of bikes lent out to users

Source

The original data can be found on the UCI database (ID = 275).

came

Computes a partitioning for a ForwardMarginalEffect

Description

This is a wrapper function that creates the correct subclass of Partitioning. It computes feature subspaces for semi-global interpretations of FMEs via recursive partitioning (RP).

Usage

```
came(
  effects,
  number.partitions = NULL,
  max.sd = Inf,
  rp.method = "ctree",
  tree.control = NULL
)
```

came

Arguments

A ForwardMarginalEffect object with FMEs computed.		
number.partitions		
The exact number of partitions required. Either number.partitions or max.sd can be specified.		
The maximum standard deviation required in each partition. Among multiple partitionings with this criterion identified, the one with lowest number of partitions is selected. Either number.partitions or max.sd can be specified.		
One of "ctree" or "rpart". The RP algorithm used for growing the decision tree. Defaults to "ctree".		
Control parameters for the RP algorithm. One of "ctree.control()" or "rpart.control()".		

Value

Partitioning Object with identified feature subspaces.

References

Scholbeck, C.A., Casalicchio, G., Molnar, C. et al. Marginal effects for non-linear prediction functions. Data Min Knowl Disc (2024). https://doi.org/10.1007/s10618-023-00993-x

Examples

Train a model and compute FMEs:

```
library(mlr3verse)
library(ranger)
data(bikes, package = "fmeffects")
task = as_task_regr(x = bikes, id = "bikes", target = "count")
forest = lrn("regr.ranger")$train(task)
effects = fme(model = forest, data = bikes, features = list("temp" = 1), ep.method = "envelope")
# Find a partitioning with exactly 3 subspaces:
subspaces = came(effects, number.partitions = 3)
# Find a partitioning with a maximum standard deviation of 20, use `rpart`:
library(rpart)
subspaces = came(effects, max.sd = 200, rp.method = "rpart")
# Analyze results:
summary(subspaces)
plot(subspaces)
# Extract results:
subspaces$results
subspaces$tree
```

Computes FMEs.

Description

This is a wrapper function for FME\$new(...)\$compute(). It computes forward marginal effects (FMEs) for a specified change in feature values.

Usage

```
fme(
   model,
   data,
   features,
   ep.method = "none",
   compute.nlm = FALSE,
   nlm.intervals = 1
)
```

Arguments

model	The (trained) model, with the ability to predict on new data. This must be a train.formula (tidymodels), Learner (mlr3), train (caret), lm or glm object.
data	The data used for computing FMEs, must be data.frame or data.table.
features	A named list with the feature name(s) and step size(s). The list names should correspond to the names of the feature variables affected by the step. The list must exclusively contain either numeric or categorical features, but not a combination of both. Numeric features must have a number as step size, categorical features the name of the reference category.
ep.method	String specifying the method used for extrapolation detection. One of "none" or "envelope". Defaults to "none".
compute.nlm	Compute NLMs for FMEs for numerical steps. Defaults to FALSE.
nlm.intervals	Number of intervals for computing NLMs. Results in longer computing time but more accurate approximation of NLMs. Defaults to 1.

Details

If one or more numeric features are passed to the features argument, FMEs are computed as

$$FME_{x,h_S} = f(x + h_S, x_{-S}) - f(x)$$

where h_S is the step size vector and x_{-S} the other features. If one or more categorical features are passed to features,

$$FME_{x,c_J} = f(c_J, x_{-J}) - f(x)$$

where c_J is the set of selected reference categories in features and x_{-J} the other features.

fme

Value

ForwardsMarginalEffect object with the following fields:

- ame average marginal effect (AME).
- anlm average non-linearity measure (NLM).
- extrapolation.ids observations that have been identified as extrapolation points and not included in the analysis.
- data.step, a data.table of the feature matrix after the step has been applied.
- results, a data.table of the individual FMEs (and NLMs, if applicable) for all observations that are not extrapolation points.

References

Examples

```
# Train a model:
library(mlr3verse)
library(ranger)
data(bikes, package = "fmeffects")
forest = lrn("regr.ranger")$train(as_task_regr(x = bikes, target = "count"))
# Compute FMEs for a numerical feature:
effects = fme(model = forest, data = bikes, features = list("temp" = 1), ep.method = "envelope")
# Analyze results:
summary(effects)
plot(effects)
# Extract results:
effects$results
# Compute the AME for a categorial feature:
fme(model = forest, data = bikes, features = list("weather" = "rain"))$ame
```

ForwardMarginalEffect R6 Class representing a forward marginal effect (FME)

Description

The FME is a forward difference in prediction due to a specified change in feature values.

Public fields

feature vector of features predictor Predictor object step.size vector of step sizes for features specified by "feature" data.step the data.table with the data matrix after the step ep.method string specifying extrapolation detection method compute.nlm logical specifying if NLM should be computed nlm.intervals number of intervals for computing NLMs step.type "numerical" or "categorical" extrapolation.ids vector of observation ids classified as extrapolation points results data.table with FMEs and NLMs computed ame Average Marginal Effect (AME) of observations in results anlm Average Non-linearity Measure (ANLM) of observations in results computed logical specifying if compute() has been run

Methods

Public methods:

- ForwardMarginalEffect\$new()
- ForwardMarginalEffect\$compute()
- ForwardMarginalEffect\$plot()
- ForwardMarginalEffect\$clone()

Method new(): Create a new ForwardMarginalEffect object.

```
Usage:
ForwardMarginalEffect$new(
    predictor,
    features,
    ep.method = "none",
    compute.nlm = FALSE,
    nlm.intervals = 1
)
```

Arguments:

predictor Predictor object.

features A named list with the feature name(s) and step size(s).
ep.method String specifying extrapolation detection method.
compute.nlm Compute NLM with FMEs? Defaults to FALSE.

nlm.intervals How many intervals for NLM computation. Defaults to 1.

Returns: A new ForwardMarginalEffect object.

Examples:

Method compute(): Computes results, i.e., FME (and NLMs) for non-extrapolation points, for a ForwardMarginalEffect object.

Usage:

ForwardMarginalEffect\$compute()

Returns: A ForwardMarginalEffect object with results.

Examples:

Compute results: effects\$compute()

Method plot(): Plots results, i.e., FME (and NLMs) for non-extrapolation points, for an FME object.

Usage:

ForwardMarginalEffect\$plot(with.nlm = FALSE, bins = 40, binwidth = NULL)

Arguments:

with.nlm Plots NLMs if computed, defaults to FALSE.

- bins Numeric vector giving number of bins in both vertical and horizontal directions. Applies
 only to univariate or bivariate numeric effects. See ggplot2::stat_summary_hex() for
 details.
- binwidth Numeric vector giving bin width in both vertical and horizontal directions. Overrides bins if both set. Applies only to univariate or bivariate numeric effects. See ggplot2::stat_summary_hex() for details.

Examples:

Compute results: effects\$plot()

Method clone(): The objects of this class are cloneable with this method.

Usage:

ForwardMarginalEffect\$clone(deep = FALSE)

Arguments:

Examples

```
## -----
## Method `ForwardMarginalEffect$new`
## -----
# Train a model:
library(mlr3verse)
library(ranger)
data(bikes, package = "fmeffects")
forest = lrn("regr.ranger")$train(as_task_regr(x = bikes, target = "count"))
# Create an `ForwardMarginalEffect` object:
effects = ForwardMarginalEffect$new(makePredictor(forest, bikes),
            features = list("temp" = 1, "humidity" = 0.01),
            ep.method = "envelope")
## -----

effects$plot()
```

makePredictor

User-friendly function to create a Predictor.

Description

A wrapper function that creates the correct subclass of Predictor by automatically from model. Can be passed to the constructor of FME.

Usage

```
makePredictor(model, data)
```

Arguments

model	the (trained) model, with the ability to predict on new data.
data	the data used for computing FMEs, must be data.frame or data.table.

14

Partitioning

Examples

```
# Train a model:
library(mlr3verse)
data(bikes, package = "fmeffects")
task = as_task_regr(x = bikes, id = "bikes", target = "count")
forest = lrn("regr.ranger")$train(task)
# Create the predictor:
predictor = makePredictor(forest, bikes)
# This instantiated an object of the correct subclass of `Predictor`:
class(predictor)
```

Partitioning

R6 Class representing a partitioning

Description

This is the abstract superclass for partitioning objects like PartitioningCtree and PartitioningRpart. A Partitioning contains information about feature subspaces with conditional average marginal effects (cAME) computed for ForwardMarginalEffect objects.

Public fields

object a ForwardMarginalEffect object with results computed

method the method for finding feature subspaces

value the value of method

results descriptive statistics of the resulting feature subspaces

tree the tree representing the partitioning, a party object

tree.control control parameters for the RP algorithm

computed logical specifying if compute() has been run

Methods

Public methods:

- Partitioning\$new()
- Partitioning\$compute()
- Partitioning\$plot()
- Partitioning\$clone()

Method new(): Create a Partitioning object

```
Usage:
Partitioning$new(...)
```

Arguments:

... Partitioning cannot be initialized, only its subclasses

Method compute(): Computes the partitioning, i.e., feature subspaces with more homogeneous FMEs, for a ForwardMarginalEffect object.

Usage:

Partitioning\$compute()

Returns: An Partitioning object with results.

Examples:

Compute results for an arbitrary partitioning:

subspaces\$compute()

Method plot(): Plots results, i.e., a decision tree and summary statistics of the feature subspaces, for an Partitioning object after \$compute() has been run.

Usage:
Partitioning\$plot()

Examples:

Plot an arbitrary partitioning: # subspaces\$plot()

Method clone(): The objects of this class are cloneable with this method.

Usage:
Partitioning\$clone(deep = FALSE)

Arguments:

deep Whether to make a deep clone.

Examples

```
## -----
## Method `Partitioning$compute`
## -----
# Compute results for an arbitrary partitioning:
# subspaces$compute()
## ------
## Method `Partitioning$plot`
## ------
## Plot an arbitrary partitioning:
```

subspaces\$plot()

16

Description

This task specializes Partitioning for the ctree algorithm for recursive partitioning.

It is recommended to use came() for construction of Partitioning objects.

Super class

fmeffects::Partitioning -> PartitioningCtree

Methods

Public methods:

- PartitioningCtree\$new()
- PartitioningCtree\$clone()

Method new(): Create a new PartitioningCtree object.

Usage:

```
PartitioningCtree$new(object, method, value, tree.control = NULL)
```

Arguments:

object an FME object with results computed. method the method for finding feature subspaces. value the value of method. tree.control control parameters for the RP algorithm.

Method clone(): The objects of this class are cloneable with this method.

Usage:
PartitioningCtree\$clone(deep = FALSE)
Arguments:

PartitioningRpart PartitioningRpart

Description

This task specializes Partitioning for the rpart algorithm for recursive partitioning.

It is recommended to use came() for construction of Partitioning objects.

Super class

fmeffects::Partitioning->PartitioningRpart

Methods

Public methods:

- PartitioningRpart\$new()
- PartitioningRpart\$clone()

Method new(): Create a new PartitioningRpart object.

Usage:

PartitioningRpart\$new(object, method, value, tree.control = NULL)

Arguments:

object An FME object with results computed.

method The method for finding feature subspaces.

value The value of method.

tree.control Control parameters for the RP algorithm.

Method clone(): The objects of this class are cloneable with this method.

Usage:
PartitioningRpart\$clone(deep = FALSE)
Arguments:

plot.ForwardMarginalEffect

Plots an ForwardMarginalEffect object.

Description

Plots an ForwardMarginalEffect object.

Usage

```
## S3 method for class 'ForwardMarginalEffect'
plot(x, ...)
```

Arguments

x	object of class ForwardMarginalEffect. See the method <pre>\$plot() in ForwardMarginalEffect() for details.</pre>
	additional arguments affecting the summary produced.

plot.Partitioning *Plots an FME Partitioning.*

Description

Plots an FME Partitioning.

Usage

```
## S3 method for class 'Partitioning'
plot(x, ...)
```

х	object of class Partitioning.
	additional arguments affecting the summary produced.

Predictor

Description

This is the abstract superclass for predictor objects like PredictorMLR3 and PredictorCaret. A Predictor contains information about an ML model's prediction function and training data.

Public fields

model The (trained) model, with the ability to predict on new data.

target A character vector with the name of the target variable.

X A data.table with feature and target variables.

feature.names A character vector with the names of the features in X.

feature.types A character vector with the types (numerical or categorical) of the features in X.

Methods

Public methods:

- Predictor\$new()
- Predictor\$clone()

Method new(): Create a Predictor object

Usage:

Predictor\$new(...)

Arguments:

... Predictor cannot be initialized, only its subclasses

Method clone(): The objects of this class are cloneable with this method.

Usage: Predictor\$clone(deep = FALSE)

Arguments:

Description

This task specializes Predictor for caret regression models. The model is assumed to be a c("train", "train.formula").

It is recommended to use makePredictor() for construction of Predictor objects.

Super class

fmeffects::Predictor -> PredictorCaret

Methods

Public methods:

- PredictorCaret\$new()
- PredictorCaret\$predict()
- PredictorCaret\$clone()

Method new(): Create a new PredictorCaret object.

Usage:
PredictorCaret\$new(model, data)

Arguments:

model train, train.formula object.

data The data used for computing FMEs, must be data.frame or data.table.

Method predict(): Predicts on an observation "newdata".

Usage:
PredictorCaret\$predict(newdata)

Arguments:

newdata The feature vector for which the target should be predicted.

Method clone(): The objects of this class are cloneable with this method.

Usage:

PredictorCaret\$clone(deep = FALSE)

Arguments:

PredictorLM

Description

This task specializes Predictor for 1m and 1m-type models. The model is assumed to be a 1m. It is recommended to use makePredictor() for construction of Predictor objects.

Super class

fmeffects::Predictor -> PredictorLM

Methods

Public methods:

- PredictorLM\$new()
- PredictorLM\$predict()
- PredictorLM\$clone()

Method new(): Create a new PredictorCaret object.

Usage:
PredictorLM\$new(model, data)

Arguments:

model train, train.formula object.

data The data used for computing FMEs, must be data.frame or data.table.

Method predict(): Predicts on an observation "newdata".

Usage:
PredictorLM\$predict(newdata)

Arguments:

newdata The feature vector for which the target should be predicted.

Method clone(): The objects of this class are cloneable with this method.

Usage:

PredictorLM\$clone(deep = FALSE)

Arguments:

Description

This task specializes Predictor for mlr3 models. The model is assumed to be a LearnerRegr or LearnerClassif.

It is recommended to use makePredictor() for construction of Predictor objects.

Super class

fmeffects::Predictor -> PredictorMLR3

Methods

Public methods:

- PredictorMLR3\$new()
- PredictorMLR3\$predict()
- PredictorMLR3\$clone()

Method new(): Create a new PredictorMLR3 object.

Usage:
PredictorMLR3\$new(model, data)

Arguments:

model LearnerRegr or LearnerClassif object.

data The data used for computing FMEs, must be data.frame or data.table.

Method predict(): Predicts on an observation "newdata".

Usage:
PredictorMLR3\$predict(newdata)

Arguments:

newdata The feature vector for which the target should be predicted.

Method clone(): The objects of this class are cloneable with this method.

Usage:

PredictorMLR3\$clone(deep = FALSE)

Arguments:

Description

This task specializes Predictor for parsnip models. The model is assumed to be a model_fit object.

It is recommended to use makePredictor() for construction of Predictor objects.

Super class

fmeffects::Predictor -> PredictorParsnip

Methods

Public methods:

- PredictorParsnip\$new()
- PredictorParsnip\$predict()
- PredictorParsnip\$clone()

Method new(): Create a new PredictorParsnip object.

Usage:
PredictorParsnip\$new(model, data)

Arguments:

```
model model_fit object.
```

data The data used for computing FMEs, must be data.frame or data.table.

Method predict(): Predicts on an observation "newdata".

Usage:
PredictorParsnip\$predict(newdata)

Arguments:

newdata The feature vector for which the target should be predicted.

Method clone(): The objects of this class are cloneable with this method.

Usage:
PredictorParsnip\$clone(deep = FALSE)

Arguments:

print.ForwardMarginalEffect

Prints an ForwardMarginalEffect object.

Description

Prints an ForwardMarginalEffect object.

Usage

```
## S3 method for class 'ForwardMarginalEffect'
print(x, ...)
```

Arguments

х	object of class ForwardMarginalEffect.
	additional arguments affecting the summary produced.

print.Partitioning Prints an FME Partitioning.

Description

Prints an FME Partitioning.

Usage

```
## S3 method for class 'Partitioning'
print(x, ...)
```

х	object of class Partitioning.
	additional arguments affecting the summary produced.

summary.AverageMarginalEffects

Prints summary of an AverageMarginalEffects object.

Description

Prints summary of an AverageMarginalEffects object.

Usage

```
## S3 method for class 'AverageMarginalEffects'
summary(object, ...)
```

Arguments

object	object of class AverageMarginalEffects.
	additional arguments affecting the summary produced.

```
summary.ForwardMarginalEffect
```

Prints summary of an ForwardMarginalEffect object.

Description

Prints summary of an ForwardMarginalEffect object.

Usage

```
## S3 method for class 'ForwardMarginalEffect'
summary(object, ...)
```

object	object of class ForwardMarginalEffect.
	additional arguments affecting the summary produced.

summary.Partitioning Prints summary of an FME Partitioning.

Description

Prints summary of an FME Partitioning.

Usage

S3 method for class 'Partitioning'
summary(object, ...)

object	object of class Partitioning.
	additional arguments affecting the summary produced.
